Abstract

One of the richest areas in minerals in Romania is the North West where there are six counties, namely Cluj, Maramureş, Satu Mare, Sălaj, Bihor and Bistriţa. Ferrous and non-ferrous deposits, salt, uranium and coal have been found and exploited here, and such deposits still exist. These mineral resources have been exploited by surface and underground mining works, production being obtained mainly through underground excavation which meant mining methods consisting of remaining voids, subsidence and backfilling. The environmental impact assessment is not known, which is also the main objective of this project. Currently Romania does not have a management plan for monitoring the effects of underground mining on the surface The paper presents a proposal of monitoring program called IMMINENT which will integrate advanced monitoring and analytical techniques in new, coordinated and innovative ways in order to improve our understanding of land deformation above former mines from the NW of Romania and it's effect on the environment related to the development of an integrated system of monitoring land degradation and risk assessment, built as a unique referred database on the IMMINENT platform; a novel model for Romania's former mines regions.

Keywords: monitoring, subsidence, integrated system.

Introduction: The research questions and the hypotheses made in the project

Currently, all mining activity in the northwest of Romania has ceased, and the mines are in preservation. But we can still see how, 10 years after the closure of the last mine in the area, no one is concerned about the effects of underground mining or what remains: mines that were closed through a more or less properly coordinated process. The execution of the closing projects was performed inadequately and superficially, leaving an adverse impact on the environment. Also, the postclosure monitoring activity was done partly and superficially, thus ignoring the most elementary rules of engineering (Radulescu, 2011).

At present, there is no project or program to monitor the effects on the surfaces of former mines and poorly preserved mines that remained after the closing. Under these circumstances, the project would constitute a milestone in a complex action meant to analyze all the negative effects on the surfaces of former mines and poorly preserved mines that remained after closing throughout Transylvania and then across Romania.

This proposal comes amid an acute lack (with few exceptions mentioned in the paper) of concern from authorities on this subject and the imminent danger that these areas pose for the population, goods, flora, and fauna, thus the whole eco-system in general. The project has been called

IMMINENT (Integrated Model of Monitoring Land Degradation near Former Mining Areas from the NW of Romania). This paper presents a summary of this project.

From the practical point of view this project will deliver an operational demonstrator that can be adapted to other degraded land regions in Romania and elsewhere around the world. This will be achieved through the combination of innovative science, implementation of modern technologies for environmental monitoring risk and data acquisition, coordinated and cohesive operational planning, and control of environment through communications networks.

Currently, all mining activity in the region has ceased, and the mines are in preservation. But we can still see how ten years after the closure of the last mine in the area, no one is concerned about the effects of underground mining or what remained. The ultimate goal of the proposed project initiated by our team is to correct this dangerous aspect of environmental protection in the area by proposing effective solutions to identify, monitor, control and report the disastrous effects that mining has on the surface. The research questions that arise in a first analysis of the problem are as follows:

1. Did the underground voids of the mines closed in Maramures have effects that can be assigned to subsidence phenomena?

Over time, while performing underground mining activities, monitoring programs have been established for surfaces located above the underground voids created by the exploitation of minerals, which were more or less backfilled, numerous subsidence phenomena being identified for the majority of mines. These monitoring programs were developed through the establishment of observation stations that functioned by taking constant data through annual measurement cycles until the closure of mines.

2. Where are these undesirable effects? What are the risk areas?

In the Maramureş mining basin, as part of the National company for precious and non-ferrous metals REMIN Baia Mare (formerly RAPb.Zn., former Mining Station until 1989), operated the following nine companies: 1. Ilba, 2. Nistru, 3. Săsar, 4. Baia Sprie, 5. Şuior, 6. Cavnic, 7. Baiuţ, 8. Răzoare, 9. Baia Borşa, which carried out their work in 57 mines with underground mining activity. All these show imminent danger of subsidence phenomena.

3. How serious is the current situation and can we estimate its progress for each identified case?

The behavior of the land above the underground voids is extremely unpredictable, and continued or low-intensity subsidence or collapse phenomena may occur, with unforeseeable effects and evolution, and also high amplitude spontaneous phenomena with effects that can be catastrophic. Figure 1 shows a case concerning the effects of subsidence from one of the mines, considering that in the county there are hundreds of such cases that we consider serious.

4. It is possible to apply modern methods to monitor the areas identified?

Tracking the evolution of subsidence and landslides with classic surveying technologies, precision angular intersections and levelling, continues to solve a number of problems of subsidence phenomena analysis. The application of modern spatial technology such as INSAR, Interferometry, Remote Sensing, Laser scanning, various sensor technologies, GNSS-GPS technologies, robotic total topographic stations, digital photogrammetry and videography technologies, is still in its early pioneering stage.

5. Are the data and information gathered in previous analyses suitable for use as a sound Geographic Information System (GIS) type management system?

The advantages of GIS in territorial spatial data management are undeniable and are proven by numerous examples coming from most countries worldwide. Since the entire analysis of the presence

and evolution of subsidence phenomena occurs in a georeferenced managed space in a given system, and the information is easily stored in informational layers, the answer to this question is affirmative.

6. Is it possible to create predictive mathematical models of the phenomena analyzed?

The development and definition of the components of a program to monitor affected land must be made keeping in mind the necessary data that would be sufficient and relevant in the construction of mathematical models on actual behavior, which could be compared with the estimates made in the definition of operating procedures for each case.

Based on what has been said, the hypotheses made in this project are the following:
Hypothesis 1. Underground mining in north-western Romania, currently closed and preserved, shows constant and lengthy danger, for surface areas above the underground voids created during operation, of subsidence phenomena of variable severity, from case to case.

Hypothesis 2. Analysis of the danger posed by each case can only be done by defining a full and comprehensive monitoring program of these areas.

Hypothesis 3. The use of different classical and modern technologies, previously presented, is not only possible but mandatory in order to cover the whole phenomenon with various dynamics of evolution and a highly volatile risk.

Hypothesis 4. The only current, modern way, with an effective price-result ratio, for the management of so much information, is GIS.

2. Theoretical aspects regarding subsidence phenomena

2.1. Subsidence in specialized literature The main body of the paper

Monitoring and analysis of deformation of land and buildings located above underground voids (subsidence, term that was coined in specialized literature), began about 150 years ago in the mining regions of Central Europe. In the first half of the twentieth century, in Central Europe, various empirical methods of modeling and prediction of deformation of land and buildings located above underground voids were applied (Radulescu, 2013; Radulescu & Radulescu 2013).

The impact of mining subsidence on the surface can occasionally be catastrophic, destroying property and resulting in loss of life (Madan, 1986).

The existence of the phenomenon of subsidence due to underground mining is a major problem in many countries with mining activity. Such phenomena exist both for coal mining, as well as mining of metals or other categories of minerals (Barry, Whittaker & Reddish, 1989).

Measurements on establishing the extent and evolution of the phenomenon of subsidence are made by determining the vertical and horizontal movements performed on the affected Earth crust (Blodgett & Kuipers, 2002).

Based on complex research in the field, various programs for prediction and decision support were launched, based on topographic determinations in situ, an example being Mining Subsidence Predication and Assistant Decision Support System (abbreviated MSPADSS) which uses object-oriented programming and the development of GIS technology components (Wang & Wu, 2004).

2.2. Subsidence management plan

Subsidence management must be flexible and able to cope with unexpected changes or uncertainties (Oszczak et al., 2003; Technical Guide to Mine Subsidence, 2011; Bell, Stacey & Genske, 2000). The management process of the mentioned phenomenon and the approvals requested by governmental authorities in the activity of exploitation of mineral resources, means that mining operators need to have a management plan for the subsidence phenomenon (Subsidence Management Plan – SMP), which must include:

- Full description of the area proposed to be monitored, affected by mining activity;
- Forecasts on expected magnitude of the subsidence phenomenon;
- Evaluation of economic and social benefits and impact of the proposed project;
- Description of the subsidence phenomena expected and actual associated impact;
- Details on proposals for consulting the affected or potentially affected communities.

The final review of the SMP project must take into account all the potential impacts on landowners and the environment. The views of the community and government agencies need to be considered during the evaluation process. The key principles that underpin the SMP are (Subsidence Management Plan – SMP; Hartman, 1992; Kratzsch, 1983):

- Transparency,
- Existence of own capital,
- Certainty.

Introduction of new management policies regarding subsidence phenomena, worldwide, was an important step in managing the environmental impact of the underground mining industry.

2.3 The criteria of rock stability in the study of subsidence phenomena

A massive underground rock excavation results in a redistribution of the natural state of tension. If rocks around mining works have sufficient strength to take the newly created tensions, then there will be no major cracks and fractures, the rock will not change its capacity and the excavations will not need supporting. Since it is difficult to achieve a comprehensive correlation of all factors influencing stability, literature provides several stability criteria, which take into account some of the factors of influence. Of those, the study takes into account those that best characterize ore exploitation. The following describes two methods for defining the stability of rocks in studying subsidence phenomena, used for stability analyzes in metalliferous deposits specific to the region analyzed (Chindriş, 2002).

Stability criterion "n". The stability of rocks according to this criterion is estimated based on the geo-mechanical features of rock by a n coefficient given by:

$$n = \frac{\sigma_{rc} \cdot \eta \cdot \xi \cdot K}{\gamma_a \cdot H \cdot K_1 \cdot K_2} \tag{1}$$

where: H - is the depth of location of mining works; γ_a - bulk density, and σ_{rc} - monoaxial compressive strength; η - coefficient according to the degree of cracking; ξ - long-term coefficient of resistance; K - coefficient of influence of moisture; K_1 - coefficient of stress concentration; K_2 - coefficient of influence of coal mining; u – rock movement. Placing rocks in a stability class according to criterion ”n” is done in accordance with **Table 1.**

Table 1: Placing rocks in stability classes according to the stability criterion *"n"*

Stability coefficient, n	Stability class	Assessment of the stability of mining works
> 1	I	Mining work is stable
0.7 <n <1	II	Average stability
0.35 <n <0.70	III	The work is becoming unstable
0.25 <n <0.35	IV	High degree of instability
n <0.25	V	The work is totally unstable

Stability criterion "S". The assessment of stability under this criterion is related to the characteristics created by the geological and tectonic phenomena and geo-mechanical characteristics of the rocks. *S* stability criterion is shown analytically by the expression:

$$S = f \cdot \frac{K_M \cdot K_r \cdot K_w}{K_N \cdot K_t \cdot K_A \cdot K_\alpha} \quad (2)$$

where f - strength coefficient of rock; K_M - coefficient depending on the fissures of the rocks; K_N - coefficient depending on the number of crack systems; K_R - coefficient depending on the shape of the walls in the mine; K_W - coefficient depending on rock moisture; K_A - coefficient depending on the cement deposited in the cracks; K_t - coefficient depending on the openness of cracks; K_α - coefficient depending on the α angle formed by the direction of mining and direction of cracks. Depending on the stability criterion *S*, rocks are grouped into several classes shown in **Table 2.**

These calculation methods allow us to create forecasts on the possibility and extent of the subsidence phenomena, which can then be validated, or not, by measurements taken in the immediate future after the production of the underground void, and then throughout the operation of the mine by installing observation stations, and finally in the post closing phase.

Table 2: Assessing stability according to criterion *S*

The value of the stability index, S	Stability class	The degree of stability of mining works
> 70	I	Completely stable
5-70	II	Stable
1-5	III	Average stability
0.05 - 1	IV	Unstable
<0,05	V	Very unstable

We already mentioned that the closure of mines in the area analyzed, Maramureş County, did not fully observe the provisions of conservation projects and the consequences can be seen and analyzed: subsidence cones, embankment landslides, slope collapses, etc. (Figure 1) (Radulescu, 2013; Radulescu & Radulescu 2013; Stefan & Badescu, 2012).

Figure 1: Effects of the phenomenon of subsidence on the surface, Săsar mine, Borcutului Valley area, outskirts of Baia Mare, a. Subsidence cone with the destruction of vegetation, b, c, d, Collapses of banks, slopes and hillsides with the destruction of vegetation

2.4. Systems for monitoring land affected by underground voids and structures in the area

Currently, monitoring the stability of land prone to subsidence and the safety of mining constructions potentially affected can only be conceived by adopting a management system for close static, quasi-static, quasi-dynamic or dynamic monitoring of the behavior over time of affected structures. In time, new systems, methods and technologies have emerged to verify the geometry, taking into account all factors, which lead to a new field, namely cinematic topography. The terms of representation of the data recorded in the monitoring process are (Radulescu, 2013):

- Determine the exact causes (climate factors), correlated with exact recording of their effects (movements or oscillations);
- Continuity of recordings in various combinations of stress conditions;
- Overview of cumulative effects;
- Detection of the influence of each stress factor;
- Minimizing errors in recording;
- Removing-reducing the effects of the environment on measurement methods;

3. Case Study: Program to monitoring the subsidence phenomenon in underground former mining areas in the Northwest of Romania: project initiation and design

Our research is based on a conceptual model of monitoring the subsidence phenomenon above the former mining industry areas from Nothwest of Romania. This project is called IMMINENT. (Figure 2)

The overall objective of the project is the development of an integrated system of monitoring land degradation and risk assessment, built as a unique referred database on GIS Type Information System platform ;

3.1 Description of the model

The model is designed as a comprehensive Systemic approach of land degradation phenomena in the former non-ferrous mining areas from the NW of Romania.The phases of monitoring system are performed gradually through specific activities (Monitoring Tasks).
Subsidence phenomenon's monitoring which occurred in former sub-terrain mining exploitation areas, now closed and preserved, can be performed through an integrated monitoring programme; methods used in this program combine from geometrical perspective the topo-geodetic methods and specific environmental methods with respect to quality assessment. The program can be fulfilled by transposal of collected data into a predictive model which can be continuously improved by the upgrade of database from the MDB GIS Platform. Our program proposal is presented below, as a set of monitoring phases:

Phase 1: Database development and programming GIS platform, presents the concept of the Deformation Information System to supported facilitate studies of mining ground deformations. The proposed modular structure of the system includes data collection and data visualization components, as well as spatial data mining, modeling and classification modules. In addition, the system integrates interactive three-dimensional models of the mines and local geology. The system is used to calculate various parameters characterizing ground deformation in space and time, i.e. vertical and horizontal displacement fields, deformation parameters and input spatial variables for spatial data classifications. The core of the system in the form of an integrated spatial and attributive database will be described. The development stages and the functionality of the particular components will be presented and modeling functions will be shown. The system created, named IMMINENT MDB-GIS platform will host as well the intranet communication site.

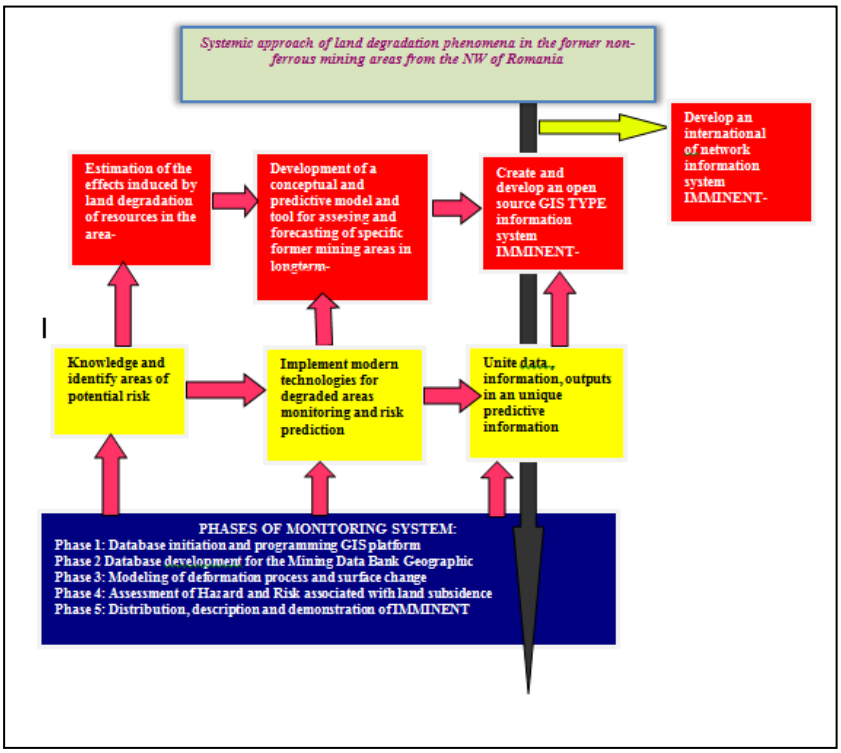

Figure 2: Model of Monitoring System of Land Degradation

This phase is operational under the following tasks (Radulescu et al., 2015):

Task 1.1.: Requirement analysis, Will analyze the volume and nature of the analytical data and graphs that will, in time, be accumulated and used in the project, the links and access to data, their classification. Similar cases of data banks, the software available in the industry, the possibility of linking in a single database all such information and the implementation of a GIS platform will be analyzed.

Task 1.2.: Data system design and development, Starting from Task 2.1.the system will be designed in detail, given the introduction, classification and sorting of data, storage and output of data. It will take into account the logical structure of the data from the data bank, quality control and data validation, analysis of access procedures and policies. Continuing the work begun in previous stages, the system will create, build and grow, acquiring software and drives required. We will initially create a demo that will be implemented, validating the design solutions developed in this task . Based on an adopted data protection policy, data will be available to partners and all members of the project team as well as external actors related to the project.

Task 1.3.: Early stage data, Until the MDB GIS data bank is adopted and implemented, data will be acquired, classified and stored on a common platform of communication, to which all members of the project team will have access under the provisions of the data protection policy. In this data bank all consortium members will load data for each activity contributing to the formation of thematic data bases, which will be then represent the base for the MDB GIS data bank.

Task 1.4.: Open source Database Maintenance, Once identified in Task 3.1., the nature, volume and sources of the data created Task 3.2., the data bank having available the data banks built in Task 3.3., the system will be developed and updated permanently, based on new data and update with the specific speed of all data in the computer system created.

Phase 2: Long term behavior tracking of degraded land

develop a new conceptual and experimental integrated monitoring system ,based on modern technologies for subsidence phenomena and associated phenomena, based on the mixed use of technologies considered classic with modern technology and with the unconventional .

Within Phase 2, the Diagnosis of the main effects of underground voids on the surface above or near former mines, especially ruptures, collapses (subsidence cones), landslides and the physic effects produced on land in the area will conduct to the identification of the most affected areas .All the information collected will be processed and catalogued. For this, a cycle of measurements shall be done - by classical but highly accurate methods named cycle « 0 »- in order to highlight the main features, the negative effects of underground mining in these areas, making it possible to classify them in terms of potential risk factors.

Phase 2 is the main fund of information that will represent the base for the Mining Data Bank Geographic Information System (MDB GIS). We will adopt and use the latest methods for structural monitoring and acquisition of physical data for land degraded by underground mining. Initially, for the five test areas chosen to collect the information necessary for the design of systems considered technology monitoring models, we shall apply the methods mentioned in the solutions of Phase 2. Thanks to the all this data we will set - for each group of case studies examined - the causes and the features-parameters that produce degradation of the surfaces above or near former underground mines; finally we will critically compare the monitoring methods used, and create technology models suitable for each situation that could occur in such monitoring actions.
Task 2.1.: Cycle "0" geometric and environmental measurements of areas in NW Romania affected by underground mining activity. This cycle will use traditional precision methods for surveying affected areas, making large scale topographical plans, and creating databases that include the parameters of environment factors caused by the mentioned activities. For the studied territories listed a catalog-database(Catalogue of the degraded land areas by underground mining in North West of Romania) will be edited (in analytical and graphical form), implemented on a GIS platform, referred to as the MDB GIS, including all areas that have undergone various changes due to underground mining, especially due to the existence of underground holes.

The test area "Masca"(figure 1) will be included in every measuring cycle (both in cycle "0" and the current cycles "1", "2", "3", cycle "4" reshaping and final cycles "5" and "6"). This area has been studied for many years by the specialized team at Technical University of Cluj Napoca(TUCN). It is an area located above the old Iara mine in Cluj County. There is a large cone collapse, and the last measurements showed that this zone is still active. So, if during the measurement cycles there will not be any spectacular moves for the other four locations chosen as test areas, the measurements from "Masca" will not only validate the new methods but will continue the previous research of the project team members.

Task 2.2.: The influence of underground mining on physical status of soils, For the same areas (except that there may be areas where previously identified mechanical effects were not produced, but there were physical effects instead) the MDB GIS database shall be filled, analytically and graphically, the data including the physical effects of such lands due to underground mining, In this stage we will define the main parameters of the effects of underground mines on the surface and describe four possible scenarios for the nonferrous metals mining activity, starting from facts, with a probability analysis for the production and the destructive cases known in the field.

Task 2.3.:New structural monitoring methods and performing of cycles measurements. We will analyze the latest structural and physical monitoring means adaptable to the analysis of degradation produced in time by the activity and then non-activity (underground voids left behind) of former mines in NW Romania. Based on the software and tools which make up these methods we shall perform test measurements for the installation, sampling and validation of each method. Starting from the classical method of observing (monitoring) the behavior of land and buildings over time,

settlements are checked with a high level of precision with optical micrometer and invar rod, through the method of middle geometric leveling, and slides are recorded through the method of angular intersection achieved with a precision theodolite. The new methods developed in this task are :

a. Structural monitoring with topographic equipment from digital generation : level, robotic total station, GPS.

b. Development of structural monitoring unconventional methods, near real-time: InSAR and Interferometric Radar Processing, Synthetic Aperture Radar (SAR) is a microwave imaging system. It has cloud-penetrating capabilities because it uses microwaves. It has day and night operational capabilities because it is an active system. Finally, its 'interferometric configuration', Interferometric SAR or InSAR, allows accurate measurements of the radiation travel path because it is coherent. Interferometric Radar Processing is a highly innovative technology for 2D monitoring of displacements and movements in slopes and structures. Monitoring of terrain movements is an increasingly important task for today's geotechnical experts required to prevent or forecast natural disasters that could affect human lives. Interferometric Radar Processing based on SAR interferometry, can remotely measure the simultaneous displacement of thousands of points over large areas (natural reflections of the slope), without the need for any kind of access to the slope under observation. IBIS-FL provides a Displacement Time Series for each point with an accuracy of up to 0.1 mm. Thanks to the high number and the spatial density of good measurement points, IBIS-FL can also provide Displacement Maps to clearly distinguish stable and moving portions of the area under investigation. The automatic acquisition and processing of Interferometric Radar Processing data enables the device to provide early warning alerts if movements exceed a selected threshold.
c. Development of structural monitoring unconventional methods, near real-time: Video gauge Digital Image correlation system, A Videography (vision based) system that can track under conditions displacements of an accuracy up to 1/100-1/200 of pixel. This for a monitoring structure translates to several millimeters (or even less). Such a system is suitable for isolated structures, mainly in the dynamic regime. The Video Gauge technology can measure multiple points on any structure, without complicated installation or re-sitting of sensors or delicate machinery

Through presented methods this task ensures also the measurement cycles which will be performed in three cycles : « 1 » ; « 2 » ; « 3 », with one month and respectively tree month periodicity between them.

The cycles of measurements allow the design of new technology models for structural monitoring and shall provide sufficient data to determine the causes that produce the degradation of land above the underground exploitations and the gravity of the analyzed situations.

General observation : All the 3 methods allow development and processing 3D digital plans, profiles and models of the measured lands. InSAR and Interferometric Radar Processing measurements of travel path variations as a function of the satellite position and time of acquisition allow generation of Digital Elevation Models (DEM) and measurement of centimetric surface deformations of the terrain.

Task 2.4.: Comparative analysis of monitoring advanced technologies; having the data from Task 2.3. will make a comparative analysis of the modern methods used, setting the possible destinations and expected performance for each. Based on this analysis will design new technology models of monitoring for both the geometrical structural part and for the environmental component. Simultaneously with the comparative analyzes made in this task we will identify, based on the data obtained, the main causes which produced the current state in terms of geometry and physical properties. These analyzes will be performed on types of extracted ore, geological structures, etc.
Phase 3: Modeling of deformation process and surface change

The observed deformation measured in the IMMINENT project and available from previous studies will be modeled in this work package, both using analytical and numerical models. The suitability of available data sets and observations of land change will be evaluated against models to be applied,

and a prioritized list of most appropriate approach to modeling decided. The purpose is to provide an understanding of the physical processes involved. Tasks proposed are:

Task 3.1: Analytical models of observed deformation

A number of analytical models are used model volcanic and tectonic deformation. Task 5.1 will consider how such models, or extended versions of these, can be applied to deformation over mining areas, considering to correspondence between subsurface pressure decrease due to mining operation, and pressure decrease due to material transfer of natural causes, such as magma flow in volcanoes. Subsidence over mining areas may be comparable to formation of pit craters on volcanoes, or scaled version of volcano deflation due to withdrawal of magma from within the volcanoes.

Task 3.2: Numerical models of observed deformation

In many cases deformation processes are complicated and require numerical models to be carried. For this purpose will use the finite element modeling using the ABAQUES software.

Phase 4: Assessment of Hazard and Risk associated with land subsidence

The scope of Phase 4 is to evaluate the likely future evaluation of deformation in the study areas, and the associated hazards and risks.

Task 4.1: Improving understanding of hazards associated with land subsidence
For each of the cased studies addressed in Phase 4, an evaluation of the likelihood of continuing movements of ground above mining areas will be evaluated, considering the deformation and the outcome of modeling.

Task 4.2: Risks related to hazards cause by land subsidence

We will consider infrastructure, housing and population in the areas of land subsidence hazards in order to evaluate the risks involved (how the hazards cause l. The aim is to understand the potential losses in a disaster that they take place

Phase 5: Distribution, description and demonstration of IMMINENT

In order to achieve the overall objectives of the project it is necessary to demonstrate that the IMMINENT system and strategy is functional, current, containing the latest tools, methods and technologies in the world. This requires testing of the database developed in Phase 1, ensuring that data flows from previous phases can be incorporated properly in the system, processed, sorted, cataloged and made available within appropriate time frames.
This phase contains the following tasks:

Task 5.1.: Validation of Technological Models, At this stage it must be proved that decision support tools are efficient for end users, including local authorities for emergency interventions. The system will be designed following a series of three cycle (« 1 »;« 2 » ;« 3 »)of measurement, performed in Phase 2, then corrected, adjusted after one more cycle tests(« 4 ») which will be done in Task 5.2.and two more cycle(« 5 » ; »6 ») tests which will be done in Task 5.3.

Task 5.2.: Test of Adjusted Technological Models, consists of:

a. Monitoring Technological Models analysis, is done by performing monthly cycle « 4 », critically analyzing each feature, parameter, result and accuracy of each model.

b. Synthesizing near and far-field data of degraded land products, This step is meant to synthesize all the IMMINENT products and, based on Task 5.1.a., the redesign, correction, adjustment elements.

c. Critical evaluation of current information flow, In conjunction with Phase 2 we will initially make a critical evaluation of new proposed technologies and then of the data flow, in the simulations of accidents caused by the worsening of the situation, in the case of pronounced subsidence phenomena.

In this process we will identify current weaknesses in information chains, making all necessary adjustments to adopted technologies and to the computer system. Outside members of the project team, the operations of this task will also be attended by an independent group of experts who will critically evaluate the effectiveness and appropriateness of new technologies adopted and the data flow and decision-making within the MDB GIS information system. We will thus create the prerequisites for the appropriate adjustment of technologies and the information system, designed to closely match the intended purpose.

Task 5.3.: Demonstration Exercise and Monitoring pilot phase,, The IMMINENT project's integration ability in real life, i.e. to monitor the situation on the ground of land in various stages of degradation due to the effects of underground mines on the surface will be done through a series of six tests, four measurement cycles, as mentioned before, after which we will design the new technology and information system, two more tests cycles : « 5 », « 6 » carried out with tree month periodicity between them, for the adjustment and correction of the system. The entire system, for both the technological part of the model methods created to monitor (using multi-criteria) lands degraded by underground mining will be related to the MDB GIS information system.

Specific Project objectives are as follows (Radulescu et al., 2015)**:**

O1. Estimation of the effects induced by land degradation on resources near the area of former non-ferrous mines from the NW of Romania, which aims to accomplish a diagnosis of land deformation (LD) in an area of abandoned mining. The LD is a process that is influenced by multiple factors associated with underground mining. The studies and description of the deformations that occur on the surface require analysis of the relationships between these factors and the registered ground movements. The relationships between these factors are complicated; therefore, their influences and combinations need to be systematically analyzed. Thus, this objective's result is to catalog degraded areas of underground mining of nonferrous metal of northwest Romania. This catalog will include two documents that will enable the test areas (test) that will continue the research, namely:

- Influence of underground mining on the physical status of soils;
- Probability density functions for land deformation parameters.

O2. Development of a conceptual and predictive model and tool for assessing and forecasting of land degradation at former mining areas in long term, which aims to develop a new conceptual and experimental integrated monitoring system, based on modern technologies for subsidence phenomena and associated phenomena, which is further based on the mixed use of technologies considered classic with modern technology and the unconventional, along with the development of new algorithms in the form of geophysical models of assessing hazards, risk, and early warnings in the event of the occurrence of disasters.

O3. Create and develop an open source information system, which aims to develop data processing and data merging in a unique database and operational platform; develop an exportable PLATFORM, procedural system and strategy for future monitoring, involving international participants datasets. Integrating this database on a GIS (geographic information system) platform. Create the MDB GIS support (mining data bank geographic information system) for the areas analyzed.

The specific objectives of the project will lead to end results consisting of the development and demonstration of geo-hazards monitoring/observing systems, and establishing comprehensive informational systems in a unique integrated database which helps stakeholders, end-users,

authorities to improve compliance with environmental legislation and prevent injury or adverse environmental effects caused by hazards.

3.2.Expected results of the IMMINENT project

- Development of a conceptual and predictive model and tool to unite knowledge of different areas of geodesy, physics soil management and simulation math in an unique predictive information (Blachowski & Stefaniak Paweł, 2013; Dubois et al., 2008; Eliasson et al., 2006; Elske et al., 2012).
-Through the research carried out in the project we will determine the most appropriate monitoring technology for LD phenomena generated by the mining activity on the surface (Erol, 2010; Geirsson et al., 2010; Gikas, 2008; Roberts, 1999; Rzepecka et al., 2011).

-Forecasting and evaluation of specific former mining areas in long-term dynamics under the action of various environmental factors. The project fills the lack of information on the devastating effects that mining activity has had in the counties in North-West Romania by studying all the affected areas, collecting data that allows both the creation of a database on the effects of mining on the environment but, also an analysis of its extent. For this purpose a database of all these phenomena will be created and implemented (graphic and attribute) on a GIS platform (Radulescu & Radulescu, 2013; Blachowski, 2013).

- Estimation of potential effects induced of soil physical degradation condition on resources in the area and assess the potential risk of degradation of environment condition of land management in the term (Blachowski, 2013; Chrzanowski & Chrzanowski, 2004; Radulescu, 2011; Trota, 2006). The project will propose and establish priorities for the authorities to intervene in order to relieve and stop the phenomena mentioned, and to correct the relevant legislation with reference to the former mining areas, how they are closed down and preserved. The project will enable us to know the phenomena in general, the mechanisms that produce and expand them, by building mathematical models that will reflect their history, establishing the causes and the contribution of each to the current state of each studied phenomenon. Multi-criteria simulation of these phenomena will form the basis for forecasting of the likely evolution of LD phenomena.

3.3. Establishing the appropriate evaluation and success criteria to determine the end-of-project results.

The comprehensive and integrated approach of IMMINENT (Radulescu et al., 2015) represents one of the main strengths of the project, because it joins all the important links in the chain from observations to end user, which is necessary to ensure the sustainability and completeness of the Romanian and European abandoned mining fields phenomena. This systemic approach can be fulfilled by a combination and equillibrum between the power of the research team, the power of technology and an. information flow to stakeholders.

3.4. Original and innovative contributions of the IMMINENT Project

By Assessment of the comparative advantages of the project outcomes with respect to the known performances of existing products, technologies and/or services.

1. No monitoring methods for the geo-mechanic –geometric phenomena were applied in kinematic regime, only in static regime.

2. There is no database on the current situation of the effects of mining on the environment in Maramureş and Cluj) - there is only analytical, descriptive data, completely isolated.

3. Lack of coherent analytical and numerical models of the studied phenomena

4. Lack of existing monitoring technological models; the measurements have been carried out only in isolated cases, using traditional static technology only.

5. The application of GIS (Geographic Information System) in this area is poor, and there is no way of implementing data (coming from monitoring the effects of mining) onto GIS platforms.

6. In general, there is lack of coherent action of managing the phenomena caused by mining, there is no value chain of communication; all information conveyed is disparate and only apply to extreme situations.

3.5. The expected impact of the IMMINENT monitoring program

The result of the project could contribute to a better quality of life due to mitigation of capital risk induced by land degradation, surface deformation and subsidence of former mining areas, which are located near human settlements. Quality of life is directly related to the impact factors regarding project contributions, which are divided mainly into:

A. Environmental impact, A historical investigation of data will allow a understanding of the real situation of land degradation due to the subsidence phenomenon. For example, proposals to reopen a mine will be analyzed and evaluated critically, regarding likely threats to the environment and the impact expected based on data obtained from the monitoring of subsidence phenomena in the area.

B. Economic impact, Sectors of the economy, such as civil engineering, energy, transport, forestry, agriculture and tourism are the most exposed to this type of degradation.

C. The impact on the government, Governments require efficient civil protection, emergency planning, effective early warning systems, access to data on all aspects of land movements, and a mechanism by which they can seek specialized advice during a crisis. The project will make available data in due time, to facilitate the drafting of national risk evaluations in the studied area.

D. Impact on social awareness. Abandoned mines have had serious social consequences, such as loss of jobs, isolation, poverty, etc. In underdeveloped areas, such as these abandoned mines, all organizations responsible must work to improve the lifestyle of people. Also, prevention made because of the project regarding disasters created by land degradation could cover significant negative effects on living conditions and contribute to the prevention of loss of lives, homes, property and goods due to the effect of land subsidence, landslides or erosion of soil.

4. Conclusions

Underground mining produces voids which have reversible and irreversible effects on surfaces and flora, fauna, constructiona, the environment in general and housing in areas located above former mines. In Soliman's (1998) vision, subsidence is "a natural and man-made phenomenon associated with a variety of processes". "Subsidence is an inevitable consequence of underground mining that may be small and localized or extend over large areas" (Hartman, 1992). Horizontal and vertical movements of the surface, even the collapse of volumes from the surface until reaching equilibrium with inner masses, damaged by exploitation, are related to the geometric component of subsidence, which is analyzed in the paper.

This paper is sounding the alarm over the lack of concern in determining the hazard presented by former underground mines in the county of Maramureș, in terms of surface movements

IMMINENT will explicitly encourage interaction and knowledge exchange between different scientific disciplines, in particular between geodesic sciences. All data gathered in the project will be made available through an open-access policy, in particular to facilitate improving national expertise and capacities in environmental advanced studies, in monitoring and data processing for developing

sound solutions for a sustainable management of sediments and soils quality and other natural resources.

From the practical point of view this project will deliver an operational demonstrator that can be adapted to other degraded land regions in Romania and elsewhere around the world and the advantage is a useful, rapid, homogenous and cost saving tool for a large category of end-users.

This will be achieved through the combination of innovative science, implementation of modern technologies for environmental monitoring risk and data acquisition, coordinated and cohesive operational planning, and control of environment in context of climate change communications networks.

A Short Survey on Non-Maturity Deposits Modelling in Slovakian Banking Sector

Mária Barteková, Comenius University in Bratislava, Faculty of Management, Bratislava, Slovak Republic, maria.bartekova@st.fm.uniba.sk

Abstract

The risk management of non-maturing deposits (NMDs), like savings deposits, sight deposits and deposits redeemable at notice, is complicated by the unknown options that customers may exercise. Given the significant amounts of NMDs in the balances of retail banks, a sophisticated management of the interest rate risk becomes a critical issue. Understanding the characteristics of a bank's deposit base is crucial to determining how interest rate changes may affect the bank's liquidity, profitability and exposure to these changes. In the current low-rate environment, limited alternative investment opportunities, and general risk aversion, the pricing of deposits and modelling the elasticity of savings volumes is a major concern for all retail banks (Moser et al., 2015).

In view of these developments and the importance of NMDs, we have conducted a survey of Slovak banks' attitudes toward NMDs modelling with the intention of determining and characterizing best practices. Especially, we concentrated our efforts on the question, if the current modelling is adequate with respect to the strategic importance of deposits. This paper aims to present the results of this survey and is based on the interviews conducted on a total of 28 banks doing business in Slovakia.

Keywords: non-maturing deposits, interest rates, modelling

Introduction

The banking environment in Slovakia has been subject to significant change since the start of the financial crisis (Majerčáková and Mittelman, 2014) and the cost of liquidity has now become an increasingly more important factor than was previously the case. The Slovakian market comprises approximately EUR 48.9 billion in deposits by households and companies. A large percentage of the balances of Slovakian banks (Papík, 2015) consists of positions without contractual maturity, the so-called non-maturity deposits (NMDs), like savings deposits, sight deposits and deposits redeemable at notice.

At first sight, the NMDs product looks relatively simple. But, on more careful examination, this product's characteristics appear difficult to capture when one tries to manage interest rate risk on the balance sheet. This is due to the following two features:

- ✓ the client holds the option to change the notional at any time,
- ✓ the financial institution holds the option to change the interest rate at any time.

How these two options are incorporated into a specific method largely determines the degree of complexity of that method. Without a defined maturity date, a defined notional and a defined interest rate, incorporating such a product correctly into measures used for the management of the balance sheet poses a big challenge. Herein lies the ambiguity of the modelling problem, and its potential unfavourable consequences when evaluating NMDs from a risk measurement perspective.

One of the most important sources to address funding needs have always been NMDs. The impact of financial crisis on the cost of liquidity and funding has strongly intensified also Slovakian banks'

motivation to simulate the long-term funding value of these shorter-term liabilities using modelling. Traditionally, NMDs are assumed to be less volatile than other funding sources. As a consequence, many interest rate risk models assume that NMDs exhibit longer durations and lower price sensitivities to rate changes than other funding sources.

To determine the duration of NMDs the replicating portfolio approach has already been described in many academic papers in the past (von Feilitzen, 2011, Džmuráňová and Teplý, 2015). This approach consists in determining the portfolio of fixed income securities (risk-free zero-coupon bonds) with different maturities and different weights and the related investment strategy that best replicate the cash-flows of NMDs. The duration of NMDs is then determined as the duration of this replicating portfolio which can be computed analytically. The maturities and the weights applied in the investment rule are to be determined by the optimalisation such that the rule performed "best" (which could be defined as the lowest standard deviation of the margin between investment return and client coupon).

Modelling Non-Maturing Deposits

Before the financial crisis, deposits were considerably cheaper than interbank lending as a source of financing for banks. But, largely due to the financial crisis, the opposite is true (Colmant et al., 2013). Today, NMDs are generally the primary source of funding for banks in Europe, representing over 50 % of their liabilities, so the manner in which they are modelled has tremendous implications when estimating their value and their impact on interest rate risk exposure measures.

Modelling and valuing NMDs is not a simple task, principally because they are not market traded. A review of NMDs modelling literature (KPMG, 2014) indicates numerous approaches for their inclusion in economic value risk assessments. The basic objective of any NMDs modelling method is to project accurately, for a given interest rate scenario, future deposit rates and balances. Regardless of the degree of complexity and sophistication applied in modelling NMDs, all methods require assumptions about how the deposits will behave in the future.

A widely-used method of NMDs modelling is the construction of the replicating portfolio (Konings and Ducuroir, 2014) by an analysis of the historical evolution of the NMDs position in the banks' balance sheet. Of course, such a method requires a set of historical data of customer rates, volumes and market rates that may be used for reinvesting or financing. The portfolio structure is determined under the assumption that the cash flows of the fixed income securities used for replication match those of the NMDs as close as possible. In other words, the average yield on the portfolio moves parallel to the client rate, and a drop in the volume is compensated by maturing instruments. In practical implementations the resulting portfolio weights remain constant over time; therefore, this method has a static character. Such method is commonly used by many European banks and has already been described in several academic papers in the past.

Affected by seasonal factors, accidental factors and cycle factors, total deposits are in the process of continuous change. A main idea behind a more advanced approach is to split the volume of total deposits into a core (stable) part and a volatile (temporary) part, where we assume that the stable component has a long maturity and the volatile part a short maturity (Figure 1).

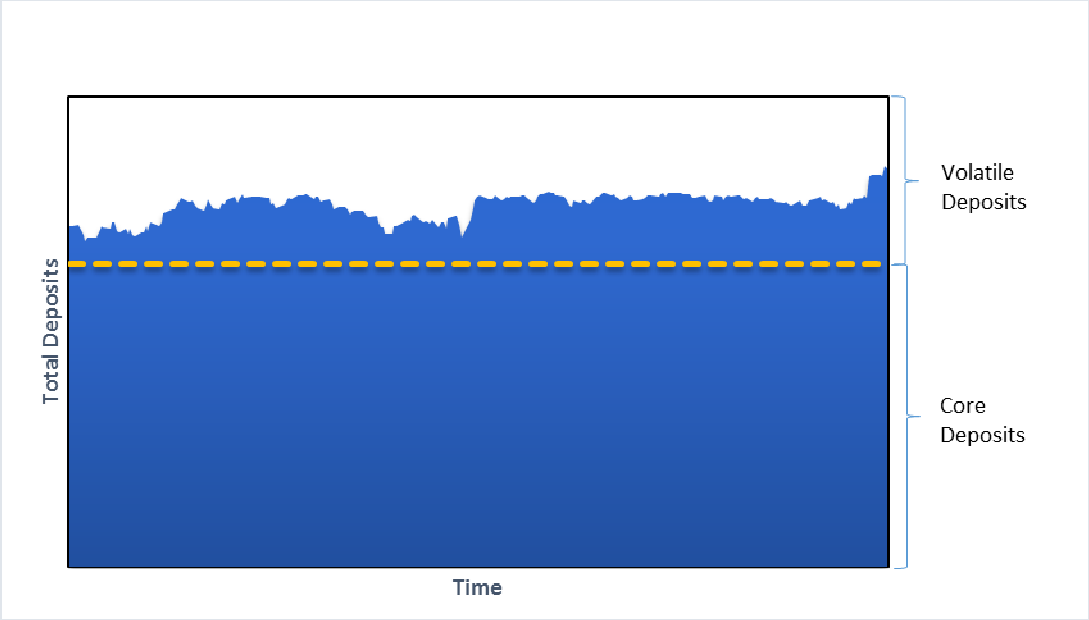

Figure 1: Example of core vs. volatile deposits

Source: own calculations

To overcome the obvious deficiencies of the conventional static replication approach, Frauendorfer and Schürle (2006) have suggested:

- ✓ instead of a constant portfolio composition and identical maturities (up to the next readjustment), the weights and also relevant maturities at which maturing instruments and a volume change are reinvested or financed have to be recalculated frequently,

- ✓ the replicating portfolio is not derived from a single historical scenario but from a large number of scenarios for the possible future outcomes of the relevant risk factors, i.e., market rates, client rate and volume.

After Frauendorfer and Schürle (2006) the motivation of the first point was to exploit the newest information from the markets and from the client behaviour; the second point requires a quantitative model that describes the stochastic dynamics of market rates, client rates and volume over time together with the dependencies between them for specific retail products.

Majority of the NMDs modelling methods that are used today, are deterministic in the sense that there is no randomness involved and only one possible scenario is considered in which the calculations are based on the historical data. In stochastic models the evolution of interest rates is described as a stochastic process. Certainly, this approach requires more computation time than analytically solvable models, but this drawback is offset by a more realistic description of risk factor dynamics. An example can be seen by Frauendorfer and Shürle (2006) who specify such a dynamic replicating portfolio approach based on stochastic optimization and compare the approach to a basic static replication.

Main Results

We conducted our survey between August and November 2015. It is based on a total of 28 banks located in Slovakia. For confidentiality reasons, in this paper neither the identity of each bank nor the category to which each bank belongs can be revealed. The surveyed institutions represent a mix of banks with:

- ✓ balance sheet size above EUR 5 billion (5 banks),
- ✓ balance sheet size between EUR 1 billion and EUR 5 billion (7 banks), and
- ✓ balance sheet size below EUR 1 billion (16 banks).

All of the surveyed banks have very similar range of business activities and statistics shown within the survey are not broken down by the size of institutions.

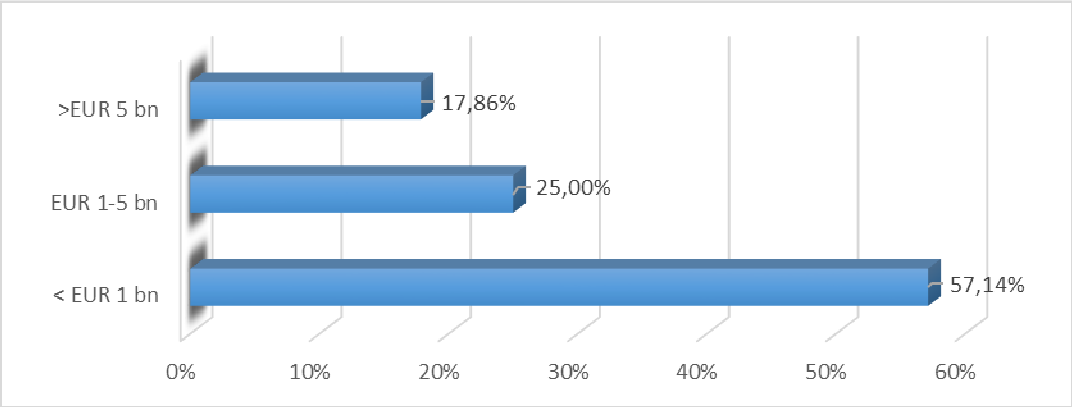

Figure 2: Size of surveyed banks, 2015

Source: own calculations, National Bank of Slovakia

Historical trend analysis of NMDs growth rates is a good start to begin when evaluating exposure to interest rate risk (Bohdalová and Greguš, 2015). Figure 3 demonstrates this analysis performed on the entire banking sector in Slovakia. Year-end 2015 shows that NMDs represented 58.9 percent of total deposits compared with a historical average (the figure uses an 8-year average as the basis for historical comparison) of 39.3 percent before the financial crisis. This shift may have resulted from clients reacting to the low interest rate environment, risk aversion, or limited alternative investment opportunities.

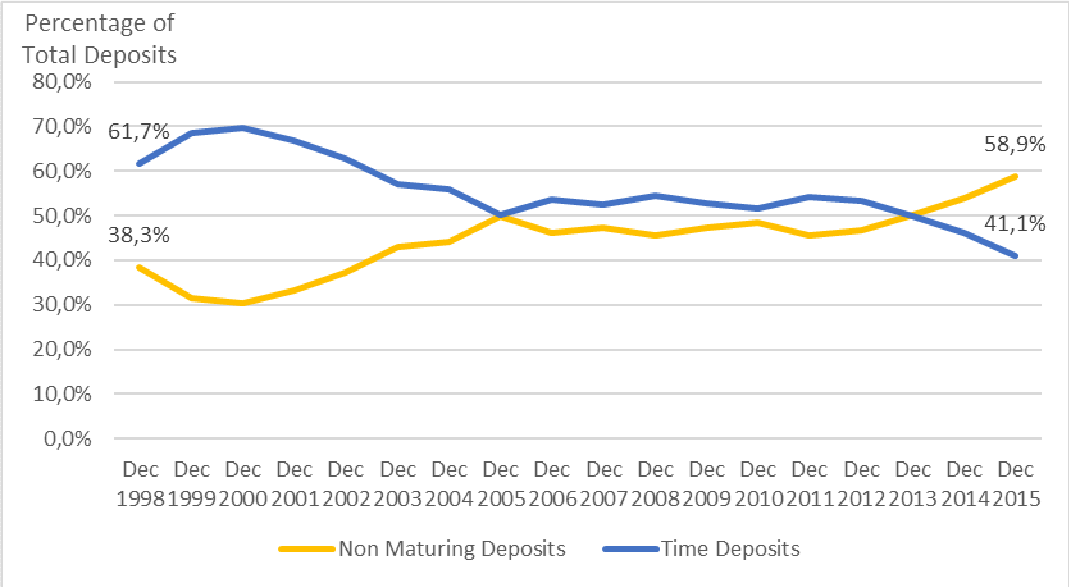

Figure 3: NMDs versus Time Deposits, 1998 - 2015

Source: own calculations, National Bank of Slovakia

As one can see from Figure 3, depositors have historically preferred to lock in higher yields through instruments with stated maturities, such as time deposits, during higher-rate environments. Since the low interest environment started in 2009, an increasing number of clients have been incentivized to move from fixed-term into NMDs and from mid-term into longer-term mortgage products. Recent central bank decisions have further intensified this development. Although NMDs are classified by the European Central Bank and the National Bank of Slovakia as so-called core deposits for regulatory reporting purposes, the inflow over the last years must not exhibit the same characteristics that traditional core deposits have demonstrated in the past (Stachová and Medo, 2013).

Figure 4 displays the evolution of the average saving account base rate in Slovakia. For illustrative purposes the evolution of the short term (3M EURIBOR rate) and long term (5Y EUR swap rate) interest rate have also been included.

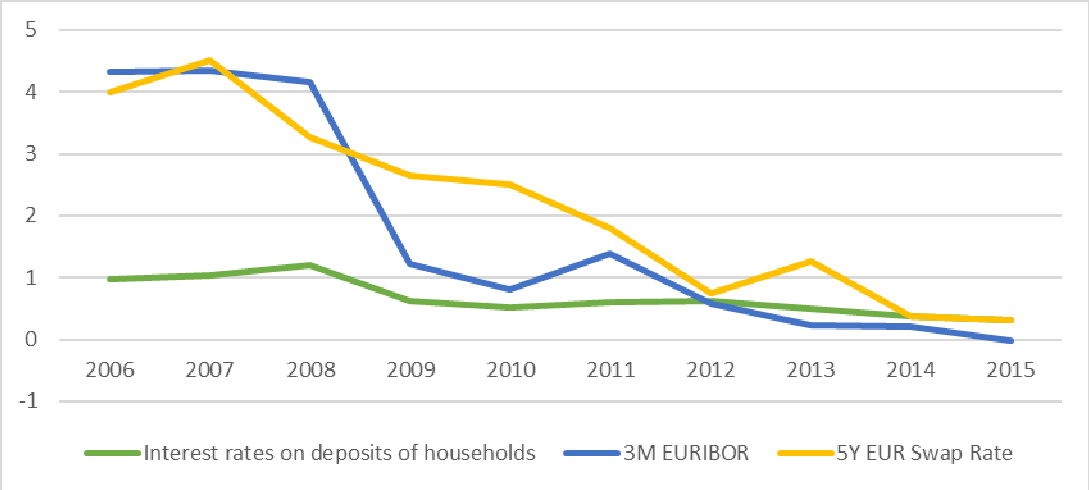

Figure 4: Average saving account rate, 2006 – 2015

Source: own calculations, National Bank of Slovakia

Among the banks where the survey was done, we have found that the risk management departments serve as a unit responsible for measuring interest and liquidity risks while finance departments have the responsibility for covering cost/benefit allocation. The importance of the NMDs models can be documented by the fact that assets-liability committees of the Slovak banks are unique bodies that approve both the initial model as well as any changes. We were able to find out the fact that the banks are trying to increase the consistency between their liquidity risk measurement and liquidity cost/benefit allocation with the objective to create a single assessment of liquidity.

All respondents agreed that all behavioural components of the NMDs models should be reviewed and tested regularly, as part of a structured back-testing framework; the implementation of objective and independent validation was seen as an important step to verify the appropriateness of all assumptions, explicit and implicit. Several of the respondents commented that implementation of this validation process could be difficult and labour intensive. Concerning the frequencies of updates and validation of analyses, our survey indicates that majority of the banks (approximately 53 percent) currently updates their NMDs models at least on a quarterly basis (Figure 5).

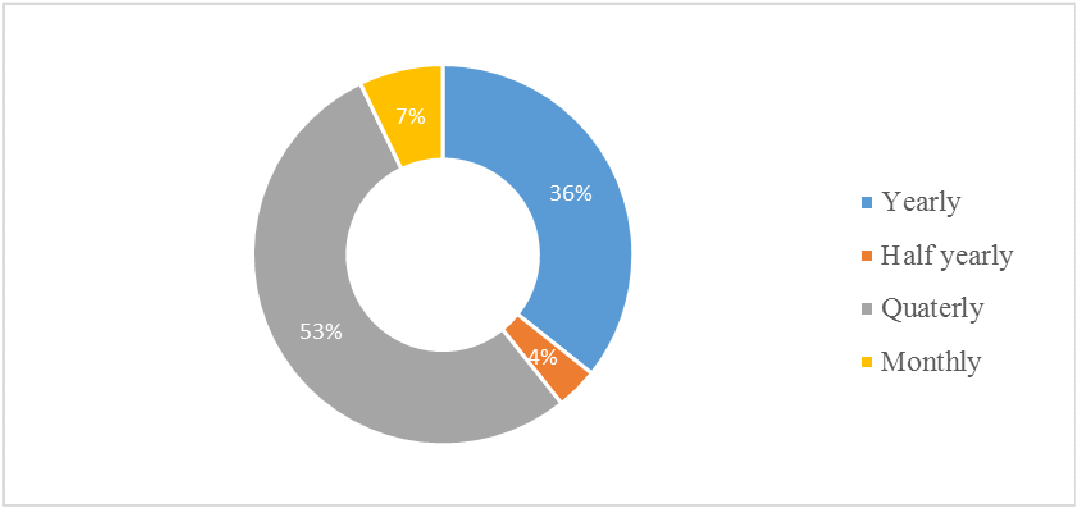

Figure 5: Frequency of NMDs updates

Source: own calculations

The model risk management process should be included in a formal policy that should be reviewed and approved by the appropriate board function. The policy should specify the management roles that are responsible for model oversight, evaluation of results and development of validation procedures. Regardless of the bank size, expert judgement is a valuable source of information in risk management. Especially, risk based decision making relies significantly on quantitative risk assessment which requires numerical data describing the initiator event frequencies and conditions probabilities in the risk model. This data is seldom found in data base and has to be elicited from qualified experts. At majority (71 percent) of Slovakian banks are NMDs models based on both expert judgment and quantitative data analysis (Figure 6). The largest of the surveyed banks never rely purely on data analysis as a basis for their NMDs models.

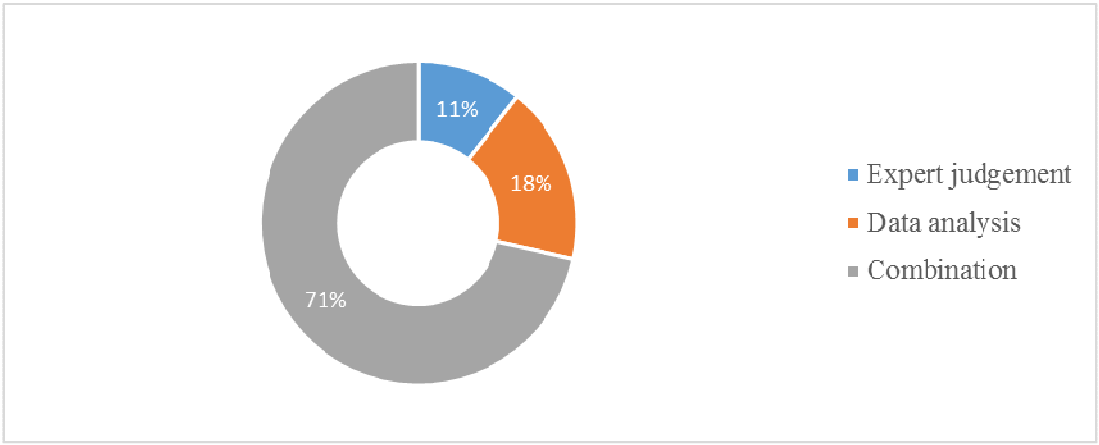

Figure 6: Input basis for NMDs models

Source: own calculations

Data analysis on the deepest level (on the account or even lower) requires a highly granular database together with a very powerful IT infrastructure. Most respondents are intimidated by high costs and high complexity of account-level modelling and therefore prefer to perform data analysis on the portfolio level (Figure 7).

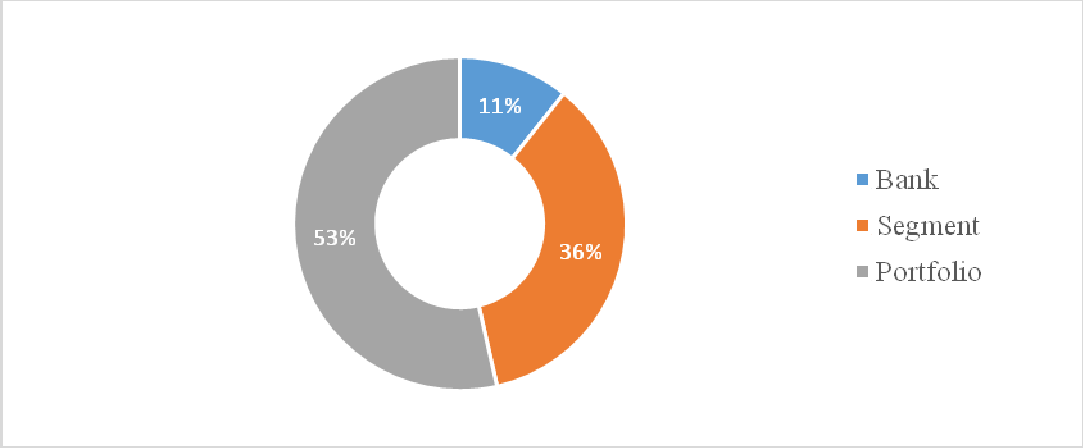

Figure 7: Granularity banks are conducting their data analysis on

Source: own calculations

Conclusion

Non-maturity deposits play a critical role in the profitability of retail banks in Slovakia. These deposits account for approximately 39,5 % of the industry total funding, directly impacting a bank's ability to lend, invest and drive earnings. Models designed to measure interest rate risk and liquidity through various rate scenarios can provide valuable forward-looking predictions. However, models results are only as useful as the embedded assumptions. Because NMDs are a very important source of funding for most Slovakian banks, assumptions related to how deposits respond to changes in interest rates are important drivers of each model results. The above results imply that senior management and the departments in charge of planning and risk management should fully understand the characteristics and problems regarding NMDs modelling to properly gauge and manage interest rate risk. Our survey shed some light on the range of practice of the NMDs modelling process for liquidity risk measurement in Slovak banking sector.

Summary

Our survey shows that most large Slovak banks rely on a static replicating portfolio approach to handle the interest rate risk of their NMDs. Some banks use or have been experimenting with more complicated modelling approaches such as dynamic replicating portfolios and models based on stochastic analyses. However, these models turn very advanced to capture the difficulties involved in this problem and the Slovak banks tend to be reluctant to implement such relatively complicated models and instead stick to less complex ones.

Our survey shows also, that NMDs are modelled on a fairly high aggregation level and banks' expert judgement as well as quantitative analysis is a significant driver for the derivation of the model parameters. The hedging portfolios for the run-off of NMDs are typically static and based on a linear regression function, though more advanced approaches can also be identified by larger banks. Our analysis also revealed a relatively broad range of NMDs modelling methodologies and practices, which, in general, we still consider to be in its infancy with significant room for improvement.
We would like to express our thanks to all the participating banks and our individual contact persons.

Abstract

The disappearance of the mining industry in many parts of Eastern Europe, and with it the the industries which developed horizontally and vertically brought many towns in the situation of many former large industrial centers in Europe, changing the economy and local identity and leaving behind areas that are destroyed and polluted, mostly abandoned, so-called Brownfield sites. Restructured, these vast areas may lead to the creation of spaces that represent a support for current activities of life, work and recreation of exceptional quality. The environmental, social, cultural and economic problems as components of the decision system support, regarding to a new urban regeneration project, should be analyzed to measure the overall impact of the new project. In this study, Rapid Impact Assessment Matrix (RIAM), which is one of the options for assessment of environmental impact (Environmental Impact Assessment - EIA) of urban regeneration actions, was used to determine the optimal variant of the two proposed for a more efficient use of the former industrial metallurgical platform CUPROM – PHOENIX, and neighboring industries in Baia Mare, Romania. Different components were used to produce a cumulative score, that is, an average score (ES) for each of the two options proposed in the project. By comparing the possible positive and negative effects produced by the adoption of each of the two versions we established a totalizing score indicating the optimal solution based on the criteria entered, the components considered for each criterion and score for each.

Keywords: former large industrial centers, Rapid Impact Assessment Matrix, urban regeneration, Brownfields

1. Introduction

One of the most serious problems facing many municipalities in Eastern Europe is that because of the excessive industialization which took place during communism, made useless by the new world order, vast areas of partially demolished industrial buildings have remained, now called Brownfield sites, black holes in any city, for which viable uses will need to be found, in view of their inner city position, coupled with explosive urbanization facing Europe today. In this regard, there are arguments stating that urban regeneration should occur by complete demolition, decontamination of resulted land and use thereof for different purposes, from green areas, deficient in most former communist towns, where providing housing to all residents was crucial, to construction of cheap housing, social cultural spaces, small traditional industries etc.

The costs are very high and, although they are justified, few municipalities have the capacity to access funds without support from outside the community or easily integrate them into a broader perspective. The authors consider that this was the real reason why brownfield land conversion has not been a very important factor in reducing consumption of new land in urban development due to the increase in population. Besides this reality also results from a report from the European Environment Agency published in 2010 which also showed that the expansion of residential areas was more pronounced than the regeneration of brownfields while the built up areas have increased more than the population growth [http://www.eea.europa.eu/ro/highlights]. This was why the concept of reuse of areas within cities has evolved over time from those interventions which initially targeted costly recovery of soil quality for reuse covering a whole range of areas in which environmental objectives are only an aspect of the intervention [http://www.urbact.eu/useact]. The new perspective was made possible by adopting integrated urban regeneration models such as CABERNET, CLARINET, RESCUE, REVIT, etc. [Norrman J. et al., 2015] which allowed a broader perspective and a useful exchange of experience in urban regeneration areas including Brownfield type areas. Thus, as shown by the Cabernet model [http://www.cabernet.org.uk/], economic affordability of "brownfields reuse" may differ depending on the direct / indirect costs of regeneration; expected / returned revenue; type of financing and financial risks involved; national and local taxes and risks related to fluctuations; development agreements between the landowner and / or municipality and developers. Each of these parameters should be evaluated carefully in the action to start an urban regeneration project.

In these circumstances the priority for 2014-2020 of the European Commission is increasing territorial cohesion by supporting Urban Development, focusing on urban regeneration.

In relation to the Baia Mare Metropolitan Area, which integrates the city and surrounding areas to the level of about 25% of the county of Maramureş, in the USEACT [http://urbact.eu/useact] project one of the most important initiatives on European urban regeneration highlighted was: "The high number of brownfields (mostly mining settlements), due to changes in the industrial sector, after the communist period". In this context, the Local Action Plan of Baia Mare has the major theme of "sustainable rehabilitation" of brownfield sites, due to the decline of the mining industry [AGENDA LOCALÃ 21]. This work is part of the concerns of the authors [Rădulescu 2016] to contribute logistically and cognitively to address this much-needed action, especially regarding urban regeneration of the Phoenix-CUPROM brownfield, the main former industrial area in Baia Mare, currently fully demolished except the tallest building in Romania, a 351,5m smoke chimeny, the third in Europe and 8th in the world, included in the current urban regeneration projects.

2. Literature Review

The concept of "Urban renewal" ("Urban Regeneration" in the United Kingdom), "Urban Revitalization" in the United States) [http://portal.hud.gov/]] has deep roots in the history of urbanism stemming from a need of redesigning crowded urban areas or areas in various stages of degradation, and it has experienced both successes and failures. The modern version began in the late 19th century in developed European countries and experienced an intense phase in the late 1940s in the work of reconstruction of cities bombed during the Second World War. Urban renewal requires relocation of businesses, demolition of structures damaged or no longer needed, population relocation and purchase of private property in order to implement urban development projects initiated by local authorities. This process is also done in rural areas [Chigbu, U. E.,2012] and implemented by territorial systematization tools, but in this case, even if the intention is the same - to reshape the current layout - the content of the actions and the means differ. Development of the concept of "Urban renewal" has been strongly driven by increasing the share of people living in cities, from 30% in the mid-19th century to 50% today; it is estimated that by 2050 every region of the globe will be predominantly urban, as regards the functional characteristics [UN-Habitat, 2008]. In urban regeneration projects special emphasis was put on creating more efficient urban structures, able to combine multidimensional interventions and promote new forms of collaboration between stakeholders involved, and create new planning and management strategies [Fernandes, J.A., Chamusca, P., 2009; Sassen, S., 2006]. Worldwide, urban regeneration has developed despite being

confronted with doubts and uncertainties due mainly to the inability to predict the future. Therefore, now, measures are being taken to ensure appropriate conditions for the personal interests of individual citizens, interest groups, and entire communities [Fernandes, J.A., 2010; Connell, D., 2009; Hall, P., 1992; Soja, E., 2009].
Over time, several versions of the concept of brownfield sites have been developed, but analyzing them one can see that dressed in other words the essence of the concept remains. Thus, Alker et al. [Alker, S., et al., 2000] has proposed a definition from a multidisciplinary perspective, defining the brownfield site as: " any land or premises which has previously been used or developed and is not currently fully in use, although it may be partially occupied or utilized. It may also be vacant, derelict or contaminated" and Dixon's version [CEQ 1978; CEU, 1997] is: "any land, which has been previously developed, including derelict and vacant land, which may or may not be contaminated". US Environmental Protection Agency (EPA) defines the term as "real property, the expansion, redevelopment, or reuse of which may be complicated by the presence or potential presence of a hazardous substance, pollutant, or contaminant" [Hao W., Chuan C., 2012].

Regarding the impact of urban regeneration of browfield sites on urban policies, a simple finding may explain fully: "About 60% of households in urban areas in the UK are built on brownfield sites and with slight variations the situation is similar in the Member States of the European Union, the United States and more recently in major cities of China [Syms, P., 1997; Adams, D., Watkins, C., 2002; Hao W., Chuan C., 2012].

Environmental Impact Assessment (EIA) is a tool used in projects aimed at the implementation of development and planning strategies being adopted and incorporated into territorial planning regulations in several countries or regional groupings, being used in most countries [CEQ, 1978; CEU, 1997; DANIDA, 1994; EBRD, 1996]. Since its introduction in the United States in the late 1960's, EIA was adopted and implemented by many developed and developing countries [Sowman, M., Fuggle, R., Preston, G., 1995; Leu, W.S., Williams, W.P., Bark, A.W., 1996; Barker, A., Wood, C., 1999; Tran, L.T. et al., 2002; Alper B., 2007]. EIA has developed as a useful tool in improving planning decisions, but has always suffered from subjective evaluations, the final conclusions of the analyzes of this type are difficult to quantify and may in the absence of analysis tools having a "domino effect", which was criticized, EIA being often seen as an instrument which lacks transparency. [Introduction to RIAM, 1998] To overcome these shortcomings in the execution and reporting of EIA Rapid Impact Assessment Matrix (RIAM) was developed. This system is based on the knowledge that specific criteria provide, that are common to all impact assessments, and by scaling these criteria, becoming possible to record the values of assessments. RIAM operates with both positive and negative potential effects [Introduction to RIAM, 1998]. RIAM has seen diverse applications in environmental impact assessment, thereby Environmental Impact Assessment of hydroelectric installations [Paulo S. F., Naim H., 2007] in various projects is aimed at environmental protection in Turkey [Alper B., 2007], feasibility studies on the analysis of urban traffic in India [Bindhu K. Jipin S., Vishnumaya K.V., 2013] or strategic environmental assessment of urban planning in China [Norrman J. et al., 2015].

3. Urban regeneration in Baia Mare analyzed in the current world juncture

Integrated urban development planning of Baia Mare for 2007-2013 materialized in the Integrated Urban Development Plan of Baia Mare in which were highlighted as priority intervention areas the neighborhoods Vasile Alecsandri and Old City, comprising the former industrial platform "Phoenix", subject to submission of projects under ROP Romania 2007-2013, Axis 1 Integrated Urban Development Plans, Sub-field "Urban Development Poles". Thus, in the context of urban redevelopment of functions of territorial units in Baia Mare, they identified five areas of urban regeneration (according to the Strategy for Sustainable Development of Baia Mare), respectively:

- Urban Regeneration Area 1 - Baia Mare Centre (Săsar River)

- Urban Regeneration Area 2 - Baia Mare North (Ferneziu neighborhood). The quarter presents major problems due to degradation, as SC Romplumb SA operates here, in an area of great landscape value, without taking into account natural and environmental risks.
- Urban Regeneration Area 3 - Baia Mare East (Old Town neighborhood), where Old Town quarter, in terms of historical, urban, architectural and environmental value, includes over 44 historical monuments of national interest (in the center), developing the most important industrial area in Baia Mare, represented by Cuprom - Central Flotation – IMMUM area.
- Urban Regeneration Area 4 - Baia Mare South (Alecsandri neighborhood) with about 40,000 inhabitants.
- Urban Regeneration Area 5 - Baia Mare West (Train Station / Warehouses neighborhood).

Now, in 2016, two years after the end of this cycle, it appears that some of the projects were completed successfully, such as the individual project "Increasing urban accessibility by modernizing Grănicerilor Street in Baia Mare", interventions in the east industrial area (of the Old City neighborhood), interventions in the cultural-historical area of Baia Mare (belonging to the Old Town neighborhood), new interventions in the center of Baia Mare (Vasile Alecsandri neighborhood). Millennium III Business Center is the greatest achievement - architecturally - in Baia Mare after December '89. By implementing the Phare project Millennium III Business Centre, the historic center of the county seat city was almost totally revitalized and was reintegrated into the local and regional economic and tourist circuit.

Besides rebuilding urban infrastructure, the project helped to rehabilitate three important buildings in the old town area, including the headquarters of the former court house. Two main problems are still unresolved, in draft form, after completing extensive and relevant feasibility studies, in terms of the urban regeneration of the city, namely two Brownfield areas, i.e. the area presented in the paper, Cuprom-Phoenix and Ferneziu-Romplumb. To better understand why these projects could not even be initiated, we must refer to the situation of contaminated sites in Romania, where there are a number of 1183 contaminated / potentially contaminated sites, currently inventoried by the National Agency for Environmental Protection. Maramureș occupies third place in the national hierarchy of contaminated sites with 109 units. These lands are public or private property, still in operation (current activity) or scrapped (past activity) suspected of being "contaminated". In this context, the National Strategy and National Action Plan for the Management of Contaminated Sites in Romania was created to address the problems of contamination of soil and groundwater as a result of human activities - past and recent - conducted on industrial sites, and to eliminate or limit (potential) risks to human health and the environment.

4. Case Study: Variants of urban regeneration of the area concerned

Variant 1. Industrial park and business incubator, SEPA

The project SEPA[SEPA, 2012] aims to promote the concept of sustainable production defined as "Community of manufacturing and services companies" which, within functional areas and through cooperation, wants to improve economic and social performance, purchase specific instruments of organization, management and infrastructure" - creating a business support area. The project SEPA aims to facilitate the regeneration of a number of production areas in accordance with sustainability criteria, thus increasing the attractiveness of these areas for Romanian and foreign investors. The project is innovative since it focuses on planning environmental sustainability of production since the design stage of organization of the production sites, rather than at the time when each individual company is determining its specific location. This approach may prove extremely beneficial for SMEs who generally do not have the scale necessary to organize sustainable and efficient production sites in terms of cost. Based on best practices and experience exchanges, the project will test a model of "sustainable production site for SMEs", applicable in any field of production, based on environmental protection and the use of renewable resources, and specific local circumstances. To implement the project, Baia Mare has initiated a feasibility study, its theme being handling and

applying the SEPA issue on the East industrial platform of the municipality, i.e. PHOENIX / now CUPROM, with a total area of approx. 55 hectares, where currently there are many buildings and installations once used for extracting metals from ferrous ores, activity which was suspended in 2009 when CUPROM went into insolvency [SEPA, 2012]. The project was also analyzed in other works of the authors [Anghel C. et al., 2013; Radulescu C., 2015].

Variant 2. Joining the IMMUM + IMUAS platform in achieving a whole, including a residential neighborhood, under the concept of new urbanism

The area in question is the one which comprises two platforms Phoenix / Cuprom and IMMUM + IMUAS, the first in a current vision of demolition and full decontamination and the second remodeled under the new urbanism principles and practices. The result would be an autonomous neighborhood, close to the old city center, 300m, about 400m from the central square, so it would fit the theme of new urbanism both internally as well as in terms of integration in the city community. The smoke chimney would be preserved as an emblem not only for the Phoenix neighborhood but the whole city. Its structure is strong enough to allow a supra-structure with upper floors comprising restaurants with rooms overlooking the surroundings, access elevators, etc. The central idea of the project, in this version, is to build housing and the necessary facilities according to distances mentioned in the above list, on the land resulting from the demolition of the CUPROM platform and remodeling of the former industrial halls of the IMMUM + IMUAS platform with other facilities which do not require a maximum distance, expanding urban planning to general urban regeneration, so these new features would satisfy both aforementioned urbanism ideas[MDLPL, 2007; FSE , 2007; Alpopi, C., Manole C., 2013].

5. Comparative analysis of the two variants of urban regeneration using the Rapid Impact Assessment Matrix (RIAM) method

5.1. Materials and methods

The process of selecting components for an impact assessment on the environment (Environmental Impact Assessment - EIA), which are then evaluated according to criteria is known as "scoping". The components are defined in four categories: PC, Physical / Chemical; BE, Biological / Ecological - BE; SC, Sociological / Cultural; EO, Economic / Operational[Wei L., Yuanbo X., Fanghua H., 2014; Hoveidi H.,et al., 2013; Pastakia, C. M. R. and Jensen A.,1998; Jensen, K. (ed). 1998; VKI, 1998; Pastakia, C,. 1998].

Important evaluation criteria are divided into two groups:

- (A) Criteria that are important for the state, and that can individually change the scores obtained;

- (B) Criteria that are of value to the facts, but which individually should not be able to change the score.

Group (A) of criteria of importance to the state

(A1) - spatial limits or human interests: 4 great importance for national / international interests; 3 great importance for regional / national interests ; 2 important for areas immediately outside the local state; 1 important only for local conditions; 0 no importance.

(A2) - Magnitude of the effect of change - measure of the magnitude of the benefit / dis-benefit of an impact or a condition: 3 major positive benefit; 2 significant improvement in the status quo; 1 improvement in the status quo; 0 no change / status quo; -1 negative change to the status quo; -2 significant negative change or dis-benefit; -3 major dis-benefit or change.

Group (B) of criteria

Permanence (B1) - a measure of the temporal state of the condition: 1 no change / not applicable; 2 temporary; 3 permanent.

Reversibility (B2) - a measure of the control over the effect of the condition: 1 no change / not applicable; 2 reversible; 3 irreversible.

Cumulative effects (B3) - a measure that reflects whether the effect will have a direct or single impact, whether there will be a cumulative effect over time, or a synergistic effect with other conditions: 1 no change / not applicable; 2 non-cumulative / single ; 3 cumulative / synergistic.

Based on these criteria, both the positive and the negative impact generated by each alternative is evaluated based on environmental, ecological, social, and economic indicators. Scores based on these ratings are calculated as follows (Pastakia and Jensen, 1998):

$$(A1) \times (A2) = AT \quad (1)$$
$$(B1) + (B2) + (B3) = BT \quad (2)$$
$$(AT) \times (BT) = ES \quad (3)$$

Where: (A1) and (A2) are individual scores for criteria in group (A); (B1) to (B3) are individual scores for criteria in group (B); ES is the evaluation score for the status quo.

To use the rating system described we create a matrix for each option in the project. The matrix contains cells that used criteria established for each defined component. ES is calculated from the above equation. If the individual ES scores can be compared they are transposed in the range (Range Values: RV).

To use the rating system described we build a matrix for each option in the project. The matrix contains cells that represent the criteria used, established for each defined component. ES is calculated from the above equation. If the individual scores can be compared, ES are transposed in intervals (Range Values: RV)

The indicators were selected by a group of experts from the Technical University of Cluj Napoca after consulting stakeholders, performing field trials on the site concerned as well as its surroundings, as well as a comprehensive analysis of future proposed urban regeneration projects. In these approaches, four basic principles were considered to guide the selection of indicators that underpin the analysis conducted in this paper:

- The requirements of the Local Urbanism Regulation correlated with the General Urban Plan for the site concerned,
- The environmental objectives set by environmental authorities at state and municipal level for the study area or the category of facility to be carried out by the project,
- The main effects identified for each of the two proposed investments possible, and
- Current environmental characteristics of the area concerned and its surroundings.

We have drawn up a questionnaire that was filled in by the residents of the area analyzed regarding their opinion on the future of the area and the last two points above mentioned and all the documents produced to date on the site were read, starting with the SEPA project to URBACT, USEACT, Integrated Urban Development Plan of Baia Mare, etc.

Based on these principles we identified 35 indicators; 11 in the PC category, 10 in the BE category, 7 in the SC category and 7 in the EO category.

Table 1: Input values and RIAM scores for Physical/Chemical(PC) components

Physical/Chemical factors (PC)		Criteria - Variant A. Industrial park						Criteria - Variant B. Res. neighborhood New Urb.					
Components		A1	A2	B1	B2	B3	ES	A 1	A2	B1	B2	B3	ES
PC1	Air quality in the area	2	-1	1	1	3	-10	1	2	1	1	1	6
PC2	Emissions of pollutants into the atmosphere	2	-1	1	1	3	-10	0	2	1	1	1	0
PC3	Odour emissions into the atmosphere	2	0	1	1	3	5	0	2	1	1	1	0
PC4	Emissions of greenhouse gases (e.g. CO_2 and methane)	2	0	1	1	3	5	0	2	1	1	1	0
PC5	Water quality in the area	2	-1	1	1	3	-10	2	2	1	1	1	12
PC6	The quality of drinking water from the municipal network	1	0	1	1	3	5	1	0	1	1	1	0
PC7	The volume of pollutants in rivers	3	-2	2	1	3	-36	0	0	1	1	1	0
PC8	Volume of pollutants in the sewage system	2	-1	3	1	3	-14	1	1	1	1	1	3
PC9	The volume of liquid pollutants that require treatment other than the one made by the sewerage network	1	-1	2	1	3	-6	0	0	1	1	1	0
PC10	Quality of soil from the site	1	0	1	1	3	5	1	1	1	1	1	3

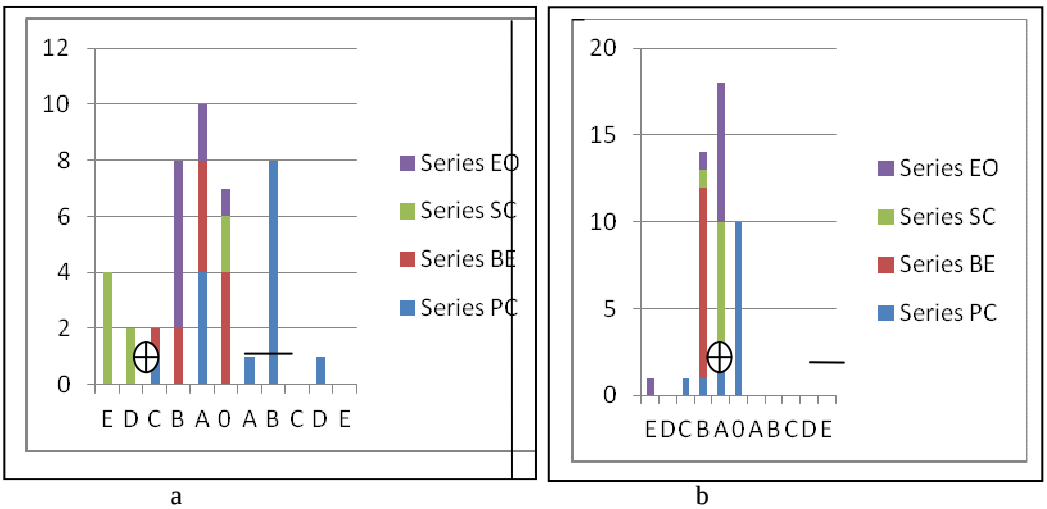
The solution	Score on the positive effects	Score on the negative effects	Score on the zero effects (N)	Total score
Variant A Industrial park	26	10	7	16
Variant B Residential neighborhood	44	0	6	44

Based on the results presented in Tables 6 and 7 we create graphs (Figure 5) representing the results of assessments made, represented graphically in a comparison.



a b

Figure 5: Representing assessment result of the first (a)and the second(b) scenario by RIAM method

5.1. Results and discussions

Whichever solution is chosen, one of the two proposed herein or any other, these steps much be taken:

1. A wider public consultation through discussions organized at municipal level of representatives of the population, especially those living near the targeted area, stakeholders interested or potentially affected by the new investment, possible investors, etc., on the future of this area, including the chimney located on the platform, which ranks third in the European ranking of the highest industrial building with 351.5 m.

2. Acquisition by local authorities of the entire land or association with banks holding land in the area or investors interested to take over the land and then participate in the project.

3. Application, in a first phase, for projects of European funding to address the following two actions further mentioned.

4. Decontamination of the area using excavated volumes, over one million cubic meters !, particularly toxic, from underground mines of Maramureş, for which no another use was identified.

5. Leveling the entire platform, after excavating the contaminated volumes.

6. Application, after bringing the area to a state of normality, in terms of the ratio between the land and environment, for projects of European funding to initiate and complete the project chosen.
It is obvious that regardless of any indicators taken into account, either of the two urban regeneration methods would only benefit the area. Starting from the current look of the area, shown in Figure , from the finding that over 100 years of metallurgical processing in the area with cyanide, sulfur dioxide and sulfuric acid, chlorides, dust containing heavy metals, lead, cadmium, etc. plus various toxic waste from the processing of results over time, any intervention to correct the status quo can only be beneficial. From the comparison of the RIAM analysis results of the two urban regeneration proposals we can establish that the winner is the second one, which does not bring - in the light of the criteria here proposed - any negative effect, achieving a favorable score compared with the other proposal that has many negative effects. Of course, the comparative analysis of the two variants stops now, because the first is already a proposal that falls, as I mentioned, in a European project, for which a documented feasibility and environmental impact study has been conducted, while the second variant is an alternative which will be considered at future analysis sessions for this large, unhealthy and highly polluted area located about 300 m from the historic center of the city.

6. Conclusions

Urban regeneration in general and urban regeneration of browfield sites in particular are mandatory actions to bring the city to a state of adequate housing. These actions are extremely expensive, financially risky, and adopting a solution to replace spaces which are vacant, abandoned, contaminated with residential, industrial, exhibition or mixed premises, following the concept of new urbanism, should be done in compliance with the natural steps of any investment, prefeasibility studies, feasibility studies, engineering design, permits, etc. The area proposed to be reshaped by regeneration, it is possibly one of the most contaminated areas in Europe and it is clear to authorities, residents and even current land owners that it cannot be kept in this state anymore.

The Rapid Impact Assessment Matrix (RIAM) is a tool used to organize, analyze and present the results of a comprehensive assessment of the impact on the environment (Environmental Impact Assessment - EIA) of projects that are proposed to be made in the analyzed environment (Pastakia, 1998). RIAM has the capacity to build more "series" to compare different options. RIAM is able to compare (on a common basis) different projects and allows both qualitative and quantitative analysis of data to be evaluated. RIAM's flexibility makes it a powerful tool for making and evaluating impact assessments. RIAM it is transparent, easily able to test various options, and still able to obtain an

overview of the solutions. The results of the various options are easy to see, which makes RIAM become a useful tool for policy makers.

Regarding the study discussed in the paper it is rooted in the area of concerns of the team at the Department of Land Measurement and Survey of the Construction Faculty of the Technical University in Cluj Napoca, to help improve life in the North West of Romania by proposing greening projects (abandoned mining areas), reuse of surface mining areas and especially underground areas, as in the case of this project, of human regeneration.

The fact that New Urbanism has won the competition in this RIAM analysis against the older and much-discussed SEPA Project should not be a surprise. Baia Mare, a former mining and metallurgical industrial center needs housing built in a modern and functional context, which only this new urban stream can bestow.

Regardless of the solution to be adopted in the end, the authors consider that Baia Mare authorities' agenda of running as European Capital of Culture for 2021 must also include urban regeneration of the Brownfields CUPROM-PHOENIX.

Abstract

In the current economic context marked by globalization phenomena, we can observe an emphasis on keeping business risk under control, therefore being developed some risk management systems, better adapted to different areas of activity. This paper highlights some results of a study made by the authors, based on literature review, the objectives being: 1) highlighting the current approaches to risk management in business; 2) identifying specific business risks. For this purpose, the current approaches are highlighted previously on the model of business risk management systems. At the same time, there are analyzed risks in various fields. Following the study, the authors clarify specific aspects of risk management systems and argue the importance of identifying specific risks from companies.

Keywords: risk management, business, global economy

Introduction

Nowadays, the business world is in a continuous process of changing, characterized by complexity, uncertainty and risks.

According to Stewart (2000), his vision about the implication of risk in business is the following: "*Risk – let us get this straight up front – is good. The point of risk management is not to eliminate it; that would eliminate reward. The point is to manage it – that is to choose where to place bets, and where to avoid betting altogether*".

Throughout time, the characteristics of the current business environment had an important role in the introduction of risk management in organizations.

The reasons for integrating risk management are mainly related to the increasing number and complexity of the risks and the organizations need for security. These possible risks cannot always be completely eliminated, but at least can be controlled so that will not affect the company (Hohan et al., 2011).

As businesses are in a continuous change, the risks are the same, so we can achieve the need of stakeholders for companies that can identify and manage their business risks.

The concerns for an efficient risk management had been intensified in the last years. It has resulted in the establishment of an appropriate risk terminology and methods supported by modern and efficient management tools.

In order to normalize the process through which it can perform the risk management, organizational structure of risk management and objectives, have been developed a series of standards, guidelines and methodologies.

In contrast with projects for which have been developed a large number of internationally recognized methodologies, in business field there is still no universally accepted procedures for risk management. The disaster management or technological field is good represented because each country creates their own standards or intervention plans, some of these being adopted as risk management procedures in business.

The risk management procedures developed for the public sector are very well detailed and formalized. Beginning from these ones, many specific elements can be adapted and used in risk management in business (Ciocoiu, 2014).

For the purposes of this article, the authors will concentrate on the current approaches related to risk management systems and from existing risks typology they will identify the specific business risks.

Research Methodology

To achieve the first objective – namely to highlight the current approaches to risk management in business – the authors have analyzed some theoretical considerations regarding the importance of the risk management in business.
Also, based on the research, the authors identify in the literature, some specific methods of identifying risks.

To achieve the second objective – namely to identify specific business risks – the authors have made a comparative analysis of the existing literature in this field.

The research was conducted in the period 2014-2015 with the support of Doctoral School from The Bucharest University of Economic Studies.

Research Results Regarding the Current Approaches to Risk Management In Business

Given the global economy and current trends, organizations face more often with various threats to their activity level. For this reason, the integration of risk management system at organization has become a necessity dictated by the business complexity and the multitude of risk factors (Bostan, 2012).

Another reason, why risk management is included in sustainability strategies, is related to the new environmental dynamics which has strongly affected the performance of the companies, in general (Mateescu, Olaru et al., 2015).

To overcome possible risks, firstly is needed their identification and analysis. Risk analysis has three steps: risks identification, risk assessment and business impact analysis (Gibb & Buchanan, 2006). The risk is present in all areas, but we will focus further on risk analysis in business.

To have control over risks in business, it appears a new concept called business continuity risk control defining the application of appropriate controls in order to achieve a balance between operational and recovery services (Nosworthy, 2000).

There is a variety of approaches in terms of stages of the process, but in a large vision, risk management supposes four interrelated processes: continue and systematic investigation of exposure to various risks and losses; assessing their nature, frequency, severity and potential impact; planning and organizing some adequate risk control techniques that minimize losses and capitalize opportunities; implementation of such techniques, internally (at department and top management level of the organization) and externally (in collaboration with organizations specialized in loss control, insurers and other specialists in the area of risk management) (Ciocoiu, 2008).

The existing business risks in the context of global economy have led to the appearance of specific standards in this field. The purpose of these standards is subjecting companies to the same rules to achieve the desired performance.

Kogan and Nikonov (2009) believe that although organizations manage different categories of risks, risk management structure is the same everywhere and a unique standard which can help reduce the risk of "*too many risk standards*".

Several approaches were investigated, ranging from alignment of management practices to full integration approaches, based on the principles of Total Quality Management. The role of The European Foundation for Quality Management (EFQM) Model for Business Excellence and Risk Management practices outlined by the international standard ISO 31000 as integration factors were investigated (Hohan, Olaru et al., 2015).

One of the standards that treat the risk management is ISO 31000:2009. According to the mentioned standard, the process of risk management begins with the establishment of external and internal context in which will take place the trial.

Figure 1 presents the risk management process which includes seven iterative elements, according to ISO 31000: 2009.

To determine the external context, it is necessary to define the company relationship with its environment, including strengths, weaknesses, opportunities and organization threats (SWOT analysis). This context includes also various stakeholders and the communication policies used with them.

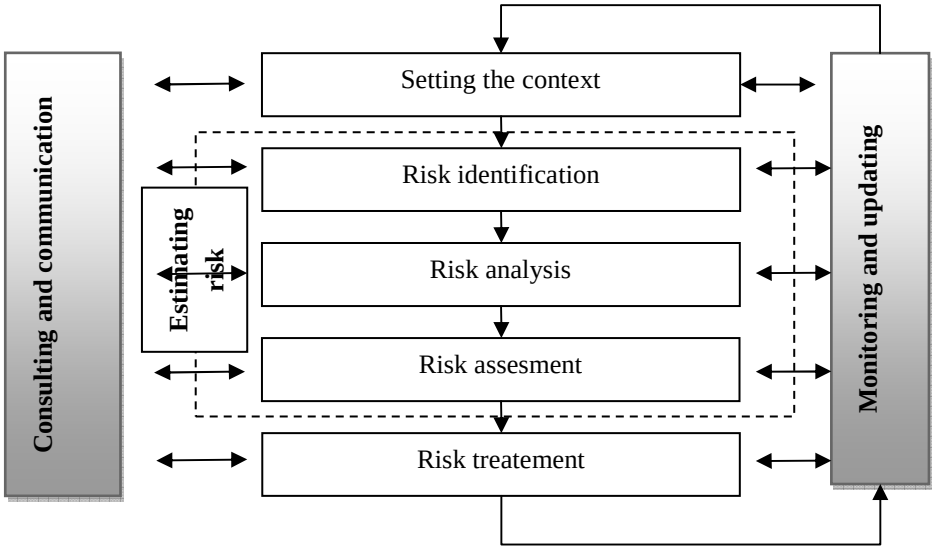

Figure 1: Risk management according to ISO 31000: 2009

Establishing internal context begins with understanding all the objectives of the company strategy to achieve these objectives and key performance indicators, the organization's mission and management structure. Also during this stage, it is advisable to identify the organization's attitude to risk. Another important aspect is the importance given to risk management and to the size of resources allocated to this process.

This stage ends the definition of risk management or risk categories with relevance to the company, departments and activities involved in risk management and its range of application, criteria underpinning risk assessment and the objectives pursued by organization during the analysis (Olaru et al., 2014). The objectives set will be used in describing the risks impact.

The risk identification involves documentation on the conditions and events that are important in achieving the organization's objectives or represent exploitation areas for competitive advantage. For their identification there are recommended the following methods: lists of risks, the experience of those involved, brainstorming, scenario analysis, flow charts and systems engineering techniques (Ciocoiu, 2014). Identifying the risks involves equally a good knowledge of the organization, of the market, the legal, social, political and cultural environment in which it operates, as well as organizational objectives (operational and strategic), including critical success factors and threats and opportunities which can arise in achieving these objectives (IRM, AIRMIC, ALARM, 2002).

Risk analysis aims to estimate risk probability of occurrence and impact. This process allows decision-makers to do a more accurate and complete assessment of the relationship between risk and potential loss or gain.
This can use several methods such as: qualitative analysis, quantitative and semi-quantitative. The characteristics of qualitative and quantitative analysis of the risks are presented in the following table:

Table 1 : Qualitative analysis vs. Quantitative analysis

Qualitative analysis	Quantitative analysis
• Estimates the probability and the impact of the risks identified to determinate their magnitude and priority. • Estimating the probability and the impact is achieved through verbal expressions or scale of values. • Tools and techniques: Matrix (graph) probability-impact; Top 10 risks; Expert opinion.	• It is often done after qualitative analysis or can replace it; • The probability and impact are determinate by mathematical models and complex computer applications; • The big and complex projects, involving advanced technologies require also a thorough quantitative analysis of risks; • Tools and techniques: Decision tree analysis; Sensitivity analysis; Scenario analysis; Simulation.

There are followed four steps in risk analysis: determine the frequency of occurrence of each risk, granting a degree of occurrence using a scale, impact assessment of that risk occurrence, scaling the severity of consequences.

Risk assessment is the stage in which are taken the decisions on the risks that require a specific treatment, by comparing the analysis results with criteria set by the organization in the setting stage of risk management context.

The most active stage is establishing how to deal with risks. Now, they are set strategies to minimize the possibility of such risks or impacts and actions to be taken otherwise.

The risk identification process involves also anticipated determination of events that may affect the organization objectives and the establishment of their characteristics.

The basic condition for the functioning of the risk management system is the correct identification of these ones. If the risk is underestimated, the level of protection would be insufficient to cover losses, and if it is overvalued, the cost of protection in excess will diminish gains from that activity. The process of risk management is defined so that all material risks can be identified, prioritized and effectively managed.

Taking into account the EFQM, DNV (2005), the process of risk management is presented in Figure 2 with the three phases.

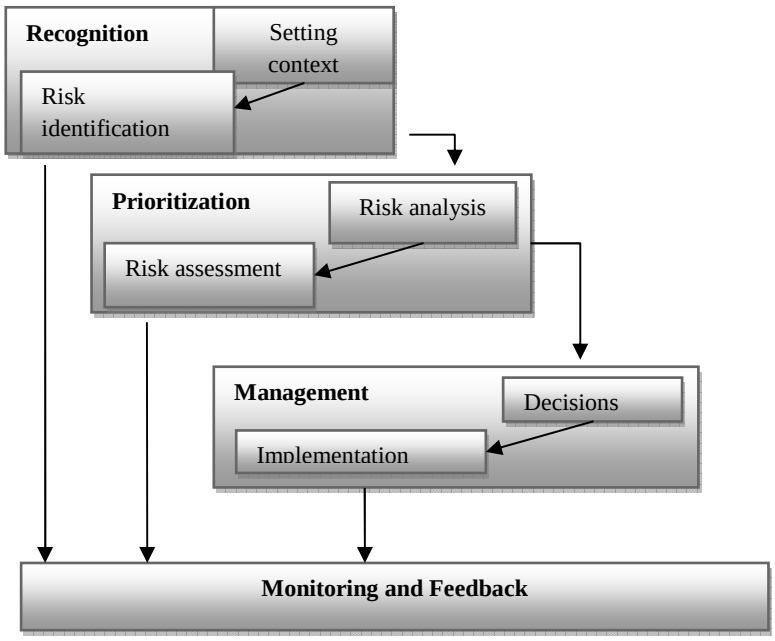

Figure 2: Risk management phases

The risk identification aims the exposure to the risk of property, rights and human resources and the hazard and potential threats that causes these exposures to risk. It involves two steps: the perception of the fact that a certain risk threatens the organization and the proper risk identification.

First of all, the risk classification is important to eliminate the confusion between the causes, effects and consequences in risk analysis. Therefore, in the following, we present the risk classification depending on determinant factors.

The 5 categories of risk resulting from risk analysis in relation to the strategy of an organization (Ciocoiu, 2014): 1) strategic risks - from the activities in a particular economic sector or in a particular geographic area; 2) operational risks - derived from various operational and administrative procedures used to implement the strategy; financial risks - come from the financial structure of the company, transactions with third parties and the used financial systems; conformity risks - derived from the necessity of compliance the laws, rules and other less formalized social expectations; environmental risks – it can be included in the conformity risks but in certain fields are very important and need to give a special attention to this category.

Depending on where the risks can be located, there are: risks related to property, risks related to staff, market risks and risks affecting consumers.

Because till now, we treated the risks depending on their specific features, we made also a classification from different criteria, and in the following will be presented some risks identification methods.

The principal stage in risk management is represented by their identification, made in different methods and using a various sort of information.

Regarding the risk identification methods, the intuitive use of manager's experience was proved to be a useless and unsatisfactory technique because manager's experience and specialization are not sufficient in this process. However, this method can be useful when it is used with other methods.

Company experts can identify a small number of risks because of their involvement in several businesses, avoiding in many cases to discuss the risks with members of other departments. They adopt this attitude to the rest of the organization just disregarding the possible impact on others. The method is recommended for companies with a risk-taking culture that propagates and uses other methods of identification.

Structured interviews were used a long time to get information from staff consultants and firms, and project or risk managers to identify risks associated with projects.

Brainstorming is a very efficient method to identify risks and establish response strategies. Specialists involved in carrying out the activity or project company, must know very well the functional and operational aspects.

Using external specialists/experts is a highly recommended method, but involves more time for the experts to become familiar with the project, organization and procedures.

The *development of some standard questionnaires* dedicated to people involved in carrying out activities is an effective method if they are adapted to each type of activity and operational area.

Another similar method is represented by *risk control lists.* These start from potential sources of risk: the framework in which it operates, personnel participating in the implementation, changes in law and economy, wrong estimates of budget and execution term.

Risk table is another method similar with risk control lists. In this table, information is structured in: threats, resources, consequences and factors which may act to modify the undesirable effects of events.

Expert systems are modern methods of risk identification, but are very expensive. Their usefulness is high for many common business risks.

Charts can be used to describe graphic and sequential the activities of a process to identify exposures, dangers and hazards. There are a variety of methods that can be used: *flowcharts, process mapping, product analysis, dependency analysis, location analysis, critical path analysis*.

These methods can show the existing interdependencies within the organization, can identify bottlenecks and determinate a critical path. They do not indicate frequency or severity of the impact, but show the minor processes with major potential of loss. A characteristic of these is that they have a limited applicability to other types of risks than that one's of the process and in most cases are too oriented toward process.

Flowcharts are represented as icons processes using predefined symbols. These separate the process in steps in order to facilitate its understanding and identifying risks.

Mapping process is similar with flowcharts, but it can use representative images to describe the process stages, and to show how are correlated the risks.

The advantages of using flowcharts or mapping processes are represented by the fact that: it provides a simple and clear visual representation of the steps involved; facilitates understanding, explaining and analyzing complex processes and associated risks and it is a precondition for using other tools.

The *analysis of fault tree* starts from a product defect or process that produces losses and presents the necessary conditions to determine the event. It highlights situations that sometimes do not present risks by themselves, but in combination it becomes dangerous for product, process and for organization. The graphical representation allows identifying risk factors, requirements or incompatible specifications, events or common risk factors (Ciocoiu, 2014).

After the presentation of these risks identification methods we conclude that there is a variety of tools that can identify risks. The condition is that we have to know these methods and choose the most suitable for our organization.

This study was realized after an analysis of the specific literature and current articles from the risk management field.

Research Results Regarding the Specific Business Risks

Through this paper, the authors clarify mainly aspects of risk management systems and show the importance of identifying specific business risks.

Before presenting the results of the analysis conducted by the authors, we first identify some considerations regarding the application levels of the risks management and management involvement.

The risk analysis is often neglected, although it has the biggest impact on business continuity. It consists in predicting the probability of risk occurrence and effects and use of obtained information to quantify the risk value. This process allows decision makers a more accurate and complete assessment of the relationship between risk and potential loss or gain.

Depending on the level of implementation risk management (basic, intermediate, advanced), risk analysis may be qualitative and quantitative or the combination of these two types. Risk management knows a multilevel implementation within organizations, depending on certain criteria. The most important criterion is the size of the organization.

In Figure 3, there are graphically represented the application levels of the risks management and management involvement.

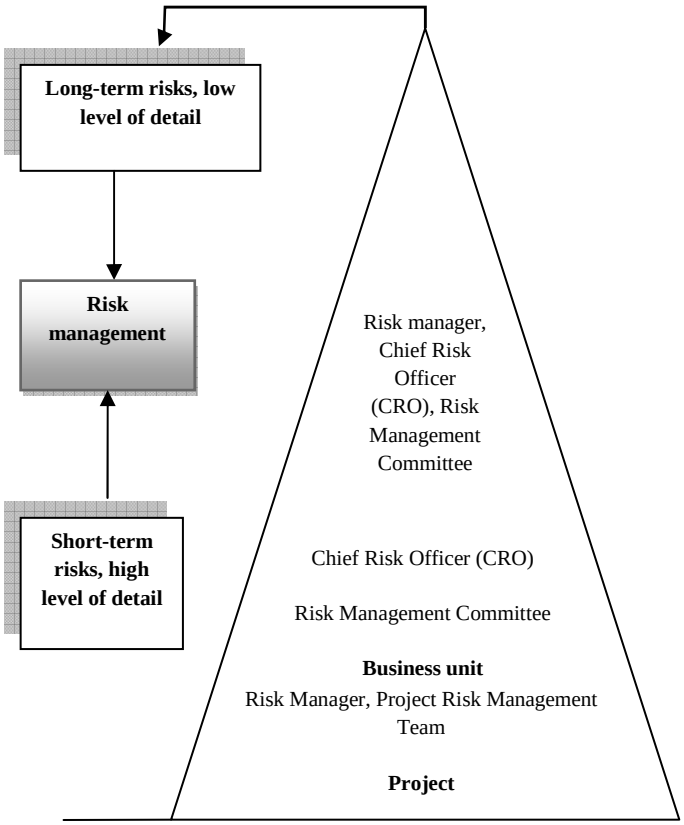

Figure 3: Application levels of the risks management and management involvement

As we can see in the figure above, there are ranked the different levels of risk management depending on the developed level: project level, business unit or corporation. Considering all items previously discussed, among companies from different fields, is established a lack of awareness related to importance of implementing risk management.

Conclusions

The results of the research undertaken showed that the risk management consists in a knowledge process of potential factors that threaten the organization's security, the measuring of their severity, reducing the effects by prevention and protection and transfer of these effects that cannot be managed at the specialized companies in risk management. It has resulted that due to a lack of awareness regarding the importance of implementing risk management in organizations, these do not face the risks.

Also be noted that we identified at the level of different enterprises the main risks: strategic risk, compliance risk, financial risk, operational risk, reputational risk and other risks.

To categorize other risks is more difficult, but here can be located the risks from the environment such as natural disasters, employee risk management and the political and economic instability which can also affect the enterprise.

Research results showed that regarding the formal organization of risk management, we cannot speak of a clear separation between general management, management of different fields (production, finance and marketing) and risk management.

On the other hand, a result of the research showed that most companies manage risks in individual management departments. Although, in the biggest companies there is a specialized department in evaluation, analysis and risk management, the newly created position serves as an intermediary for traditional functions of the organization management.

Abstract

The integration of Information and Communication Technologies (ICT) in the tourism industry is an essential element for the success of any tourism enterprise. ICTs provide access to information of tourism products from anywhere and at any time. Tour companies may also reach out to target customers around the world through a series of emerging technologies.
This paper aims to make a review of the main key factors of ICT in Tourism. Aspects such as the quality of the website, Digital Marketing, Social Networking, Multimedia, Mobile Technologies and Intelligent Environments are discussed.

Keywords: ICT; tourism; e-tourism; m-tourism.

1 – Introduction

Analyzing the whole process involving the tourism sector, we can see that its evolution over time is based on technological advances, as well as other social, economic and geographic factors.
Tourism is an important economic activity for any nation and to the world economy and it is not indifferent to technological progress, making use of it for the optimization of its business. Perhaps it was the sector that has suffered the most changes due to technological developments.

The rapid development of ICT in general and the Internet in particular has dramatically changed the tourism industry. It is widely accepted that the Internet serves as an effective marketing tool for tourism. It is a tool of importance both for suppliers and consumers for the dissemination of information, communication and procurement of goods and services online. The rapidly increasing number of users and online transactions provide clear evidence of the popularity of the Internet.
The Internet has forced the reorganization of the tourism sector through the disintermediation and re-intermediation (Machado & Almeida, 2010).

According to (Buhalis, 1998) ICT is the driver of the tourism industry:

- Cost: increases efficiency; low distribution, communication, and labor costs; flexible pricing.
- Market: satisfaction in the upmarket demand; flexibility in operating time; expertise and support differentiation; provides last minute deals; accurate information; It supports relationship marketing strategies for frequent / invited passengers; rapid response to demand; multiple integrated products; profit management (marketing strategy for profit maximization through overbooking, differentiation in the price); business intelligence; market research.
- Competition: business networks management; training of value-added; flexibility; acquisition of knowledge; strategic tool; barriers to entry.

In the following sections we present a set of technologies and ICT applications which are evidence for the tourism industry, being considered as challenges and trends.

2 - Website Quality

In recent years nothing seems to have changed the tourism sector more than ICT and the Internet. The massive diffusion of e-business and increased competition at the global level caused a dramatic rethink the ways in which the tourism business is thought, with destinations come into this competition. ICTs have become a key factor in competitiveness, not only of organizations but also of the destinations, since a wide range of technological developments caused this evolution. Apart from this fact, the availability of more effective ICT will strengthen businesses and destinations, efficiency and renewal of their communication strategies (Salgado, Godinho & Milheiro, 2012).

For Rababah et al. (2011), and a wide range of academics, quality, web-design and usability are the three main types of evaluation to be made to the websites. According to Rababah et al. (2011) a website should try to meet the customer's needs to ensure visitors and gain their loyalty. The quality factors on the web seem to have an impact on the acceptance of the user, since these factors influence the beliefs and behavioral intention of the user. In addition, the company can have control over these factors.

According to Jung et al. (2000), an electronic trading system is a type of information system. Recently, a number of studies have approached the development of applications for e-commerce and identified a number of features to be taken into account. For example, Liu et al. (2000) identified some key factors in the development of e-commerce sites. These key factors consist of the quality of information, quality of service, the playful character, the quality of the system design, and system usage. In this study, Liu et al. (2000) found that a well-designed Website would lead to better memory by the user and the recognition and a positive attitude to the Website and its products.

In recent years, several authors have been working on models for assessing the quality of Web sites, including methodologies (Bevan, 1999) (Brajnik, June 2001), (Oehler & Biffignandi, June 2008), (Signore, September 2005), (Zhang Zhu, Greenwood, & Huo, November 2002), frameworks for quality (Cornelia, Craig, Angus & Paul, May 2001), (Olsina & Rossi, 2002) (Yen Jen-Hwa Hu, & Wang, 2007) estimative models (Li, Li & Li, Sept 2009), (Olsina, Lafuente, & Rossi, May 2001), standards (W3C, 2006), usability criteria (Nantel & Glaser, 2008), metrics (Calero, Ruiz & Piattini, April 2005), (Liburne, Devkota, & Khan, 2004) (Nielsen, 1993) and web assessment tools (Ivory & Hearst, 2001) (Jati & Dominic, 2009).

3 – Digital Marketing

Currently, the market segmentation is such that tourism producers have to know how to adapt their offer almost at the moment of the reservation, so it is necessary to constantly adjust the product to the huge range of niches and existing market segments. IT tools help to thoroughly explore the tourism product, as they provide a use of space with almost no restrictions, showing all the characteristics of the products, through videos, personalized space, possible configurations and decorations, different meals, leisure packages. And further, allowing it to be up to the customer himself to 'draw' the product tailored to your needs, selecting a menu with all the possibilities that those best suited to their profile. Given that a Website can be the "packaging" of the tourism product, its presentation is often responsible for the purchase decision, so it must constantly innovate content and make the site what the customer really demand, so as to convert, the first click, a query in an effective sale (Machado & Almeida, 2010).

The best way to think about the use of ICT in the tourism industry is to discuss the tourism product characteristics and specificities of the tourism marketing. Typical for the tourist product is primarily its complexity, unique ability to meet consumer needs, dependence on time and place, a broad spectrum of quality, price relationships, dependency cooperation and the human factor. All aspects of

the tourism product characteristics and specificities of the tourism marketing are strongly influenced by the use of ICT. ICTs are changing the tourism market by supporting the tourism marketing.

ICT change the way organizations distribute their tourism products on the market (Buhalis & Licata, 2002), (Buhalis, 1998), (Frias, Rodriguez, & Castaneda, 2008).

ICT is a powerful tool for market research, neural networks are used for market segmentation, it is common to use software to analyze the historical guest / preferences on web pages.

The ability to forecast the demand of tourism can provide an advantage of important market. Song & Li (2008) proposed a detailed study of the different approaches to achieve a tourism demand forecasting through modeling and forecasting. They analyzed studies and articles on modeling and forecast published tourism since 2000 and concluded that:

- Quantitative forecasting techniques can be divided into three categories: time series models, econometric approach, and other methods, including techniques for artificial research;
- New trends to increase the accuracy of forecasting further include a combination of quantitative approaches and the integration of quantitative and qualitative approaches;
- Future development: better calculation based on seasonality, unexpected events, life-cycle assessment of tourist destinations;
- According to the authors, "there is no single model that consistently exceeds other model in all situations."

4 – Social Networks

Social networks ceased to be just the meeting place between friends who have not seen each other for some time, or a place to make new friends. Social networks grew and became something enormous in terms of interaction and communication. Social networks have a crucial role in the voyages of users, from planning the trip to sharing the experience. Formerly, the vacation destination was chosen through the catalogs of tour operators and the reliance on travel agents. That changed, now people seek on the Internet all the information about the place or places they want to visit before traveling and often seek suggestions of places to go on holiday, thus creating the vacation package that really satisfies them.

According to Digital Marketing (2015), Social Networks are one of the most powerful tools of today in tourism. Using these tools for travel related purposes has grown considerably, with Facebook, one of the most popular on number of monthly visitors. In tourism and travel, the views and recommendations of the tourists are of great importance for the growth of a company, for people to travel, take pictures, make videos of a particular locality that when added on Social Networks can arouse interest other users. According Brusha in (DigitalMarketing, 2015), there are some opportunities that should be considered in the use of Social Networking in tourism:

- New clients: Using new channels different from the usual increases the probability of reaching new people, and may well gain new customers;
- Effective communication: Knowing what they say about themselves on social networks, and participating in the communication, the company attracts and enhances its relationship with current and potential customers, through an image of credibility and trust;
- Pass the word: The so-called "word of mouth", a powerful source of dissemination in tourism. People who are on Social Networks related trips are eager to relevant and original information. When obtained, it is easily passed to others, thereby obtaining a "viral effect";
- Management of online reputation: through being present in social networks and constantly monitoring and controlling them, the company can manage the image of your brand on it;
- Fun Technology: the tourism area has an excellent opportunity to use all the tools and applications online that can help you create unique and entertaining content (videos, articles,

photo albums, discussion groups, online events, contests, etc.) that, in turn, can help attract potential customers;

- Partnering with brands that complement their own services: Depending on the area, making partnerships with online travel agencies, transport companies, restaurants, activities companies, hotels, etc., can complete their presence and offer on Social Networks;
- Disseminate a region: Any business in the tourism sector is set in a particular region that people want to visit and meet, so it is important to awaken the visitor's curiosity, so it is not confined to knowing your hotel or restaurant. Social networks should also be used to promote and advertise your region, stimulating the Internet user greater curiosity by visiting the same.

According to the study "Digital Channels in Travel" conducted by Deloitte leisure travel companies are failing to fully capitalize on the business opportunities offered by social networking platforms. The work of Deloitte, to Facebook, recommends that the travel companies that integrate digital channels into their overall business strategies to reach consumers more effectively. The study results are based on analysis that Deloitte performed the data from a global survey, sponsored by Facebook, involving 10,500 users of social networks.

5 – Multimedia

The Multimedia is also one of the development of key areas that influence tourism. The information on tourism needs a great representation of pictures and graphics, in order to provide a tangible image or experience for those planning trips. The use of animations and videos can enhance the wealth of information and interaction. Unlike information offline, which is unilaterally exposed to travelers, the Web allows people from around the world can interact virtually with a destination using the three-dimensional concept (3D) virtual visits. Experience in computer-mediated environment can simulate actual visits and virtual experience can provide almost real experiences. Interactive websites have been adopted by online merchants to attract online consumers, encourage online shopping, and to create loyalty (Fiore, Kim, & Lee, 2005). Tourists can obtain tourism information displayed from digital maps with aerial and satellite images in two dimensions and even three dimensions.

Tourist services, given their intangible nature, cannot be made available or experienced prior to their acquisition, so the review is dependent on the existing information in the printed and audiovisual forms. A tourism product of success will depend on an extensive and targeted marketing, leading to the creation of new distribution channels. ICTs provide opportunities to expand the business in a geographical, operational and marketing level. Virtual exhibits and digital photographs, based on multimedia and interactive nature of the Web, give a new dimension to the marketing of tourism destinations (Buhalis, 2003). A multichannel and multimedia system Destination Management serves goals, not only distribution and information planning for travel, such as education and entertainment, essential for sustainable development of tourism. In this sense, Hadzic (2004) argues that every tourist destination must be accessed through an integrated Web portal rather than a fragmentation of individual web pages of the different stakeholders (travel agencies, tour operators, hotels, services).

Not replacing presential tourism, Virtual Tourism has recently started to appear. This phenomenon has become possible by the combination of some technological material such as increasing Web access speeds, showing in recent years the appearance of increasingly powerful compression codecs that have decreased considerably the weight of the contents. In addition there are techniques and tools able to create immersive environments where it is possible to manipulate the visitor viewing the interactive space, seeing him in a highly personalized way. This phenomenon led to Google Company investing in Google Earth and Google Street View. The virtual tours are not a relatively new technology, however, only recently has there been a more extensive use of this kind of services and they are being used by various types of industries such as the housing, restoration and museums. The virtual tours are still relatively little interactive, using multimedia can make this an even more enriching experience. Taking as an example the Smithsonian natural history museum in the city of New York, you can make a virtual visit appealing by making use of various multimedia resources. To better engage with people power, they would use sound effects in each of the dinosaurs showing them

how they would sound at the time. Using videos or simulations would be possible to show how they walked and finally through textual elements and images the user can consult information on the subject that you certainly arouse even greater interest (Santos, 2014).

6 - Mobile Technologies

The progress of mobile technologies, especially in recent years, has enabled the emergence of new mobile services (Martin, Alzua, & Lamsfus, 2011). Mobile phones are now used to access the Internet, to create and view images and videos, to locate people and places and as learning tools and social share information with friends. The mobile phone has evolved from a traditional voice communication device to an instrument that facilitates interaction (Kenteris, Gavalas, & Economou, 2011).

The rapid growth in the use of mobile devices (mobile phones, Personal Digital Assistant (PDA), portable computers) and increasing wireless network coverage have been promoting the access to the internet via mobile devices, making it possible to suppress the space limitations time access to internet. A report from the Pew Internet & American Life Project predicts that by 2020 mobile devices will become the world the primary means of Internet access (Anderson & Rainie, 2008):

- The information models adapted for mobile guides - making use of user profiles and / or collaborative filtering techniques to deliver customized content and services; ease of updating of the information model;
- The architecture used - the chosen technology platform for the implementation of the application; they can be distributed massively to the current mobile devices;
- The communication infrastructure type used (eg, Wi-Fi, Bluetooth and 3G) - Application adaptability to changes in the network; the cost of use for users;
- Positioning technologies and map systems used to support users - if the maps support the search paths and the dynamic adjustment of routes; types of location-based services that are available; the navigation technology provides information according to the user context;
- The mechanisms used for input and output of data; typology of content available; multilingual support;
- Available differentiating services and how services are implemented based on standard or proprietary frameworks.

The evolution of mobile technologies and infrastructure has increased the requirements for ubiquitous access to tourist support systems. With advances in ubiquitous computing, the proliferation of wireless communication technologies and the increase in data transmission rates, the availability of processes of multimedia content on mobile devices has increased and become more efficient and effective (Biuk-Aghai Fong, & Si, 2008).

The use of mobile devices in tourist activities gave rise to the m-Tourism. The m-tourism has been designing in various aspects such as (Doller, Kockerandl, Jans, S., & Limam, L., 2009):

- In support of travel, allowing access to the target route and the time required estimates;
- In location-based services (LBS), enabling the maps query, store location, weather and tourist destinations in a given region;
- In electronic tour guides, allowing access to travel tips, prices, features and tourist attractions;
- In alerts about events systems, such as the opening of the boarding gates or performing scheduled activities for a certain time;
- In traffic services, enabling the consultation of traffic conditions and alternate routes.

7 - Intelligent Environments

An intelligent environment (Aml) is a vision that has promoted the enrichment of space, making it dynamic, adaptive, transparent, where the traditional computer and its traditional inputs and outputs disappear (Sadri, 2011). The first reference to Aml was introduced in 2001 by the European Union (Ducatel, Bogdanowicz, Scapolo, Leijten, & Burgelman, 2001), as an evolution of technology. And recalling the history of the computer, it was an object initially very expensive, difficult to understand and use, a rare and precious resource, and each one was used by various individuals. From the 80s we witnessed the massive use of this resource, and each individual wore one or more.

There are several projects that attempt to explain this concept in several areas, including home, office, transport, industry, entertainment, tourism, recommendation systems, health and safety (Cook, Jakkula, & Augusto, 2009). With regard to tourism, we can see projects that explore public spaces equipped with different technologies to collect, analyze and make decisions. We can also find scenarios to support the tourist during his visit, either to museums or historic sites or even those who help planning a visit to a city. And considering that the tourism activity can be divided into three phases (Watson, Akselsen, Monod, & Pitt, 2004), planning, tourism and souvenirs, the concept can also be explored in these three stages, either helping the tourist to do planning or guiding tourists during their activity, and even promoting and enriching their memories that can later remember and share.

Public spaces embedded with technology offer added value to the tourist, for a person who moves out of its usual area of residence, making it more interesting, more sociable, more beautiful and effective (Veenstra, Kanis, Groen, Meys, & Slakhorst, 2011). The project Itour (Alizadeh, Veenstra, & Kanis, 2012) is an example that explores this concept, and it investigates the potential and the acceptance of the use of technology to collect, discover and interpret data on the movement of tourists, their behavior and experiences in the city of Amsterdam, in order to provide tourists with better services.

Sadri (2011) describes in his work the use of the Aml concept in the context of museums, historical sites and in the context of a visit to a city.

Associated with the concept of Aml, and research in tourism, we find references to smart cities, and another concept called the Internet of Things (IoT) (Buhalis & Amaranggana, 2014; Wang, Li, & Li, 2013). These data show a path, trying to not only create discussion on the subject, but also to present results about experiments conducted with users as residents or tourists. In this context, services are installed in different places in the city, for example, an airport or a hospital or hotel services which contribute to the local economy and its development, tourism, the environment, energy and transport. And in the tourist level, smart cities can also offer information and infrastructure to achieve a set of solutions related to tourism. Moreover, from the physical and virtual integration (Conti, Das, Bisdikian, Kumar, & Zambonelli, 2012) and services of smart cities, tourism can take advantage of the fully integrated market with the tourist attractions, government departments and information and services relevant companies in order to promote tourism development (Kehua, Jie, & Hongbo, 2011).

8 – Conclusions

The survival of touristic organizations depends in large part on the appropriate use of new technological applications. However, the biggest challenge these will overcome is the traditionalist view that these new applications serve only large companies, focusing all their attention on applications and solutions appropriate to its size and its position in the market.

ICT plays a crucial role in the operation of the internal management of the organizations, however, establishing relations with its external environment, allowing in the case of tourism coordination between all stakeholders in the tourism system is possible.

The future of tourism will naturally be focused on technologies centered on the user that will support organizations to interact with their customers in a dynamic way. Consumers are increasingly

powerful in the developing and are increasingly able to determine elements of its tourism products. They are also much more sophisticated and experienced and therefore are much harder to please. Innovative tour companies must have the ability to divert resources and knowledge for consumers and provide greater added value to transactions. The development of new applications enables suppliers and destinations to improve their efficiency and streamline their communication strategies. Innovative technologies support interoperability, customization and constant presence. Agile strategies are needed both at strategic level and tactical management to ensure that the opportunities and challenges driven by ICT have advantage for tourism organizations to increase their capacity for innovation and competitiveness.

Motivation, a key variable within brand management

Valentina Iuliana Diaconu, University of Economic Studies, Bucharest, Romania,
valentina.iuliana.diaconu@gmail.com

Abstract

Motivation within the consumtion of products or services plays a very important part in brand management, because this variable can be one of the keys towards understanding and attracting consumers towards a brand. Motivation represents a key element of consumer behavior, an element that can determine whether a product is bought or not. Motivation is determinded by the existence of an unsatisfied need (Cătoiu și Teodorescu, 2007), being the result of economic, social, political and psychological factors. It is based on memories, experiences regarding the buying process, recommendations, elements that determine individuals to keep buying products or services for which there exists a motivation of consumption (Arnould, 2002). This paper's fundaments consist in an ongoing qualitative research regarding motivation, that has as its objective the study and understanding of certain motivational aspects regarding luxury clothing buying behavior. This study will present a series of atributes that luxury consumers or nonconsumers take into consideration when they decide to wear a unique clothing item. In order to put the subject at hand into perspective model has been constructed that shows the importance of motivation within brand management, a model that can be correlated with later results from the ongoing qualitative research.

Keywords: motivation, brand management, consumers, relations, personality, brand.

Introduction

Along with economical development buying behaviour has become harder to measure. Brand managers have to create marketing strategies adapted to each market segment so that their brands become more competitive, earning market shares and notoriety. Understanding consumer motivation is undoubtedly essential when increasing loyalty through advertising or growing a brand's personality or improving a brands reliations with consumers. There are a large number of questions to which motivation can offer answers. Why isn't motivation stable? Why do people so ofthen change consumption behavior? What are the decisions that a marketer must make when there is a need for increasing market share for a brand? What resides in the consumers „black box" and how can the motivational centers be triggered? All these questions are in fact parts of the process through which brand management tries to attract more consumers.

Consumer motivation through the perspective of brand management

Motivation refers to the behavioural manifestations of an individual in the process of buying and consumption of goods or services that can be determined by the appearance of a state of tension, due to the existence of an unsatisfied need. Motives represent variables that can influence buying behavior, in the same time representing the result of biological, social and physical factors (Cătoiu and Teodorescu, 2003). Motives are characterized at a multidimensional level, are delimited by the biological and social, by states of internal tension and knowledge. Buying or non-buying motivation is influenced by the individual's needs: the need for safety, food, self-improvement, understanding or empathizing, the need to explore and learn (Maslow, 1943). Motivation can represent the ability to make right decisions when individuals have relevant information and have high hopes for a products

or service (Hoyer and MacInnis, 2010). Consumers also have social needs: social experience, the need to communicate with others, the need to belong to a group, the need to gain a certain status or position within society, the need for authority, safety, but also the need that results from the pleasure of negociating. (Foxall and Goldsmith, 1998). Motivations can be, on one side, aspects of the individuals' uniqueness, and on the other side, a social and cultural variable. The structure of motivations can also be determined by other characteristics such as the amount of positive or negative experiences of an individual that influence buying behavior (Arnould and others, 2002). Motives can be utilitarian when individuals wish to satisfy immediate needs or hedonist, when the client regards the buying experience from a positive perspective and enjoys any activity related to shopping (Fischer and Arnold, 1990; Hirschman, 1983). Taking into account the hedonist motives, 5 segments of buyers have been determined: minimalists, collectors, suppliers, enthusiasts and conservatives (Arnould and Reynolds, 2003). Motivation can result from an acquisition that is based on the product's identity and significance. The purchase is concentrated on the logic followed by each individual: the influence from friends and family, social and economical pressure, advertising and unique design (Levy's, 1959). The challange in brand management comes from the impossibility of knowing if a consumer needs a certain product and creating a need where none exists, eventually causing pleasure as a result of use.

Motivation can make brands stronger than established competitors, because consumers prefer to use products that respect international standars of quality, morality, but also satisfy their needs (McClelland and Burnham, 2000). A strong brand needs a strong image that captures the essential, the story of a brand. Achieving a high degree of loyalty towards a brand is the main objective in the management process. Loyal consumers are very important for the company because it is much more costly to recruit new customers (Keller, 2003) and that is why motivation is key. Consumers can also be motivated to consume a certain brand if the brand's personality is humanized, or if they perceive the brand as a trustworthy partner in consumption. Brands are created to influence potential users through their identity, image or reputation (Balmer and Greyser, 2003).

Conceptual model and hypotheses

The ongoing qualitative research has as its objective the identification of variables that influence the buying motivations of luxury clothing items. In order to study consumer behavior through a motivational perspective a conceptual model has been established in order to analyze motivation in relation to the process of brand management.

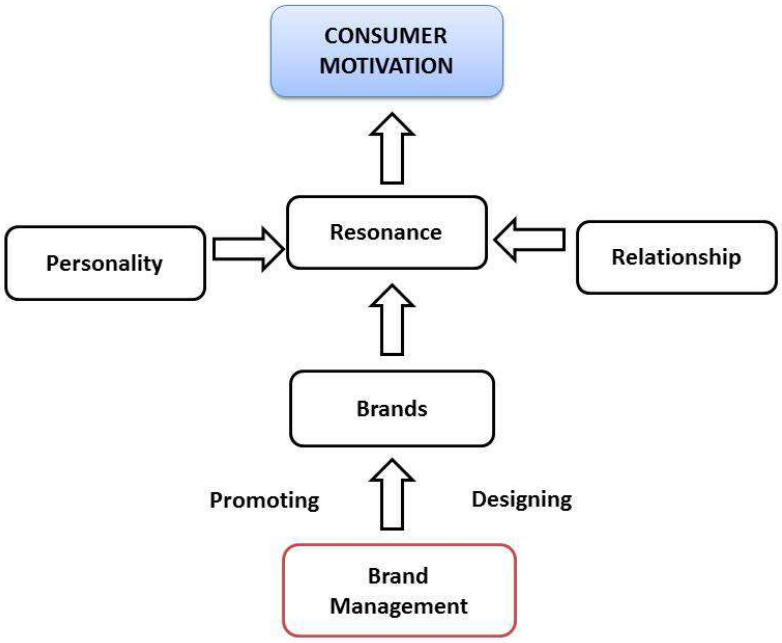

Figure 1: Conceptual model of analysis of consumer motivation from a brand management perspective

The conceptual motivation found in figure 1 illustrates the manner in which consumer motivation influences brand management. The process starts from the primary phase of creating a brand going up to the way in which the brand resonates with consumers. The brand's identity has to be strong in order for people to remember it and want to buy it or return to that certain company (Keller, 2013). After this stage, the key attributes that differentiate the brand from its competitors must be identified, because this way the decisions behind the buying process can be identified along with a pattern in which brands are classified. In order to show these aspects a communication and promotional strategy must be elaborated in accordance with the brand's identity and personality. Regarding the brand's personality, consumers tend to be closer to brands with human personalities (Keller, 2001). Furthermore, the relationships between brand and consumers must not be neglected because they need to be established as bonds of trust between partners. The moment a brand has reached peak levels of resonance with the client, one can say that a profound bond has been created at a psychological level, one that can include repeated purchases, the adoration of the brand's products, the feeling of belonging to a group but also the feeling of active implication.

Research results

The paper at hand briefly conveys a first point of view of the qualitative research regarding the purchase motivation of luxury clothing items. The qualitative research was conducted through 20 in-depth interviews with respondents within the social categories A, B, C1, women and men, with average or above average incomes, age between 21 and 60. Responses have been interpreted with a content analysis taking into account several criteria such as the 5 personalities of a brand (Aaker, 1997): emotion, sincerity, cognition, sophistication, inflexibility.

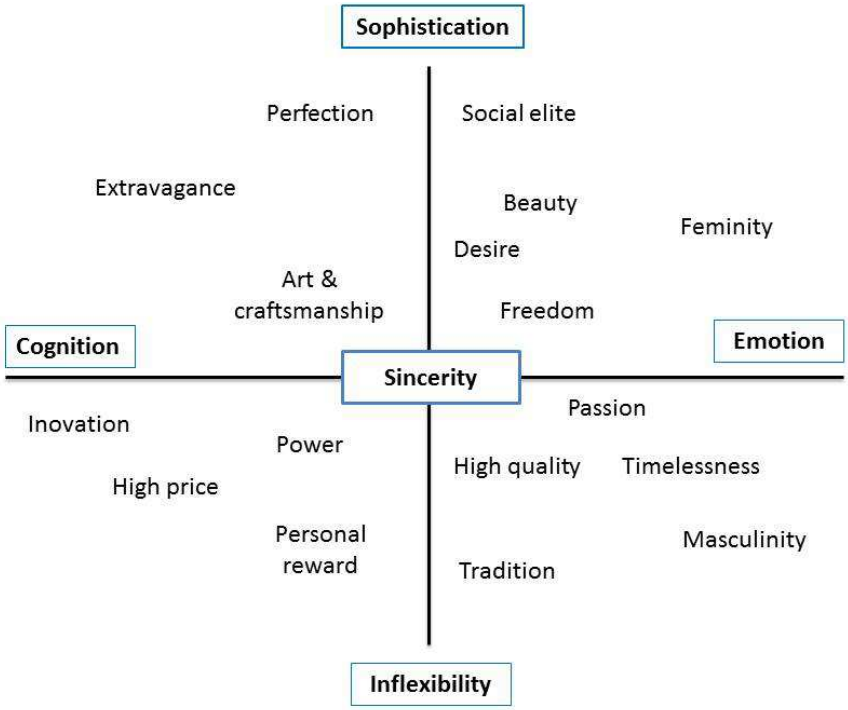

Figure 2: Personality type map

According to the figure above it can be deduced that the respondents of the qualitative research can be sorted according to the 5 types of brand personality. The attributes that were mentioned the most as being taken into account by the individuals were the ones positioned closest to the center: freedom, art and craftsmanship, passion, power, innovation, high price and desire. Given the fact that the subject was related to luxury products, respondents highlighted different motivations than the ones attributed for common goods. Even though at the beginning of the interview participants were quiet and unsure, once the discussion went on they became relaxed and interested, even identifying themselves with the research's resulting projections.

Conclusions

Consumer motivation represents the key variable in brand management because knowing the behavior of potential clients can determine the success or failure of an existing or newly created brand. Using the results of a content analysis brand managers can capitalize on the obtained information and make the necessary decisions for improving or developing their brand's image. Consumers are much more receptive to changes that take place within the market and are careful to choose the brand or product closest to their needs and expectations. They are heavily influenced by emotions, past experiences but also the media. Thus the results of the qualitative research can be a real support for brand managers in establishing marketing plans and strategies, because motivation can offer them essential information about the consumer's „black box".

Abstract

For the entrepreneuers and his family is a transfer of the family business to his successors an important strategic challenge. Family business succession process is specific for each family and is influenced by many different factors. Due to the historical development of the Czech Republic, which in the Communistic period did not allow private property, the Czech entrepreneurs stand before a completely new challenge for them, how to transfer their family businesses to the next generation? The paper is focused on the issue of family business succession, with an emphasis on its tax effects. The choice of the family business succession form has on the predecessor and his successor significant tax impacts. The aim of the paper is to identify and compare the tax effects of the family business succession from the perspective of the currently valid legislation in the Czech Republic. The research findings show a significant impact of the legislation on the tax liability of family businesses in the succession process.

Keywords: Family business, family business succession planning, tax effects, SMEs

Introduction

Family businesses are an engine of a healthy economy and hold a significant position in world trade Hnátek (2015). The family businesses are closely related to the process of family business succession planning. The issue of family business succession is according to (Cabrera-Suarez et al, 2001) a crucial and in many cases long lasting process that may absorb the attention and resources of a family for years. Mussolino and Calabro (2014) state numerous examples around the world show that succession is also a challenging process that may businesses struggle. The reason of these fights may be according to Wilson (2013) the fact that there are involved two fundamental elements, the financial and the sentimental elements, which may not be always consistent.Wilson (2013) claims it is important to attempt to preserve both the family harmony, or at least status quo of same, and the future vaue of the company. Sharma (2004) states it is difficult to establish, in particular, the right timing, finding the right successor, and managing the succession process in a fortunate way. A number of authors (Harris, 2007; Wilson, 2013; Michel and Kammerlander, 2015) stress the need for the use of experienced and trusted advisors in the process.

The issue of family business succession is very current in the Czech Republic, because the vast majority of entrepreneurs, who started their business after the Velvet Rebolution in 1989, has reached or is conciderably closed to retirement age. For Czech entrepreneurs is the family business succession process an entirely new challenge, because in the duration of Communism was not private property allowed. The issue of family business succession is very difficult, because in each case has its own unmistakable specifics related to the family relationships among the participants of the process. The family business succession process has besides to a variety of other factors also significant tax effects, which is paid the main attention of authors in the paper. There entered into force the New civil code (Act No. 89/2012 Coll, civil code), since 1st January 2014, which significantly influenced and changed the taxation of family business succession. Our research questions were:

- What are the tax effects of family business succession?
- Are there different tax impacts according to the choice of the ownership transfer?

The main aim of the research is to identify and assess the tax effects of family business succession process from the perspective of the currently valid legislation. The summarized information should help to Czech entrepreneurs in solving these specific situations, which have so far not able to meet in the condition of the Czech Republic.

Family Businesses

The definition of family businesses is currently one of the most debated issues. Authors across the approaches agree that family businesses may be small, medium or large. There are also approaches that examine the involvement of individual members of families, their shares on the ownership or control of the company.

Barnes and Hershon (1976) point to the fact there is something most deeply rooted in transfer of power than impersonal business interests. The human tradition of passing on heritage, possessions, and name for one generation to the next leads both parents and their children to seek continuity in the family business. Beckhard and Dyer (1983) characterize the family business as the system that includes the business, the family, the founder and such linking organizations as the board of directors. Chua et al (1999) state the family firms can be defined as a business governed with the intention to create a vision-driven business, which is helded in the framework of the dominant coalition controlled of the same family. Furthermore, it is also reflected in the behaviour and potentially sustainable across generations. Poutziouris et al (2006) define the family business as a business run by the founder of a descendet and with the intent of keeping the business in the family. Miller et al (2007) define that "*family business the ones in which more members of the same family are involved as the principal owners or administrators, simultaneously or in the course of time."*

Family business succession planning

Ward (2011) claims the main reasons of many family business failures are the errors in the process of family business succession planning. Harris (2007) point out to the fact that if potentional succesors are unmotivated, uncooperate and disinterested in the family business in the business when it is still governed by the current owner, then with high probability the transfer of ownership to these individuals end up for the family business as disaster. Coleman (2011) points out to the statistics, which show that 30% of family-owned businesses survive into the second generation, 12% into the third generation and only 3% into the fourth generation.

Barton (1993) states the family business succession planning can be divided into 10 partial steps, which significantly simplifies this process. These steps include: (1) gather and analyse financial and legal data; (2) contact the client´s attorney; (3) determine the value of the business; (4) compute projected estate and transfer taxes; (5) gather personal and personnel information; (6) identify dispositive and financial goals; (7) analyse the needs of family members; (8) identify potential ownership and management successors; (9) make recommendations, modify goals and provide methodologies and (10) assist the client in implementation.

Family business according to Ward (2011) do not succeed, mainly because: (1) markets and technology change; (2) competitors quickly copy successful strategies; (3) overtaking with outside buyer willing to pay more to acquire the company than it is worth and owners are unable to resist the premium to sell out; (4) lack of financial capabilities, and (5) lack of staff skills.

The issue of family business succession Schwendinger (2011) defines as transition of ownership and leadership from one member of the family to another. Schwendinger (2011) also points out that the family members must be satisfied with the process but so should non-family members'

employees. The main aim of the research was to investigate the role of the non-family employee in the succession process of family businesses. Solomon et al (2011) focused the qualitative research study, which analysed life-story obtained from 10 family business. The main aim of the interviews was to identify experiences of businesss owners and better understanding the complexities of family business succession. Gilding et al (2015) stated that issue of family business succession planning contained in literature is focused on two main motives: family business continuity across generations and family harmony. As a key theme in the context of family business research literature is very often occurs in succession planning, which is the central theme and which puts particular emphasis on ensuring the contiuity of business. Liu et al (2015) focused their research on the nepotism in the succession decisions in the context of family businesses. According to the authors of the succession often leads to a decline in performance because leaders frequently choose family members as their successor, a form of nepotism. Giarmarco (2012) states family business succession planning involves complex questions of law, tax, and business planning. The only way to find the best business succession strategy for a particular family business is to work closely with a lawyer, accountant, and a financial advisor experienced in business succession planning. According to Giarmarco (2012) is succession planning critical if the owner plans to retire in 10 years or less. In connection with family business succession are also often struggles between various interest groups and the sucessors themselves.

A number of authors (Miller, 1998; Avloniti et al 2014) are devoted to the sibling struggles or the role of gender (Wang, 2010; Koffi et al 2014a; Koffi et al, 2014b). Miller (1998) on case studies points to the fact that filling the shoes of a good leader is never easy and that this difficult situation may be even more complicated thanks to fights about the position of successor between siblings. According to Wang (2010) in family businesses, succession is very much biased by gender and daughters are almost always excluded as candidates. In the paper author provided a review of the literature on daughter succession in family businesses. Avloniti et al (2014) deal with siblings' rivalry and its impact on the succession outcome within family enterprises. Authors point to the fact that, sibling rivalry plays a critical role in the succession process, but there is only limited literature that addresses to this important issue. Authors defined the main areas that the most affect this rivalry, which include: the parental behaviour and attitude during childhood, sibling characteristics and the perception of parental fairness by the successor. Koffi et al (2014b) in their research reveal the key factors of a successful succession. The attention of the research was focused solely on the men (the predecessors) and ways to increase the legitimacy of his successor. The predecessors focus especially on the supporting the development of the successor skills, on the transfer of responsibility on his shoulders, on the support of his authority and on the efforts to demonstrate the ability to be a successor and to be respected. Koffi et al (2014a) focused their research to the issue of family business succession planning. The authors point to the fact among the factors influencing the success of the generational transition is the credibility that must be earned by the successor in the eyes of the employees. Such credibility appears to be the determining factor for ensuring a lasting success of the business. Based on this premise, a comparative study involving seven cases of succession was conducted by authors. The research findings show that men and women business owners adopt different behavioral strategies in order to bring credibility to their successors.

The tax effects of family business succession

Dascher and Jens (1999) stress the family business succession is also a significant taxing challenge. It is therefore surprising that only a small part of authors (Dascher and Jens, 1999; Tralka, 2003; White et al, 2004; Giarmarco and Grassi, 2008; Giarmarco, 2012; Walny 2012; Gillis, 2012) is interested in the issue.

Tralka (2003) state there is two main methods of the transfer of ownership. One of the methods is a method, when the transfer of ownership shall be object of taxation, and the second method - tax-advantegeous method. Although it may sound obvious, which is the more attractive option, the most appropriate transfer method actually depends on several factors, including owner´s personal plans and the business´s financial situation. White et al (2004) emphasize that devising and implementing

an effective family business succession strategy requires much more than simply estimating the value of the business and buying life insurance to cover any transfer taxes due or to "equalize" the estate among all heirs. This approach according to White et al (2004) skips too quickly to identifying and solving the liquidity need. According to Giarmarco and Grassi (2008) it is necessary to ensure at the same time the five leves of family business succession plan. One of these important levels is also minimizing the transfer taxes and to prepare an appropriate estate plan.

Giarmarco (2012) states every family business owner is going to have to decide when it will be the right time to step out of the business and how he will do it. The family business succession can be according to Giarmarco (2012) devided into three main issues: management, ownership, and transfer taxes. The research is addressed to all of these issues and describes many of the techniques business owners can use to transfer their businesses to the next generation while minimizing both family discord and transfer taxes. According to Giarmarco (2012) it is estimated that more than 70 % of family-owned businesses do not survive the transition from founder to second generation. Focused on the third issue of family business succession planning the author state that estate taxes alone can claim up to 35 % of the value of the business, frequently resulting in a business having to liquidate or take on debt to keep the business afloat. To avoid a forced liquidation or the need to incur debt to pay estate taxes, there are a number of lifetime gifting strategies that can be implemented by the business owner to minimize (or possibly elimitate) estate taxes. The research summarizes the fundamentals of business succession planning to help family business owners assess their goals and consider the economic, legal, and tax implications of various plans. According to the author is important to focus primarily on minimizing the gift and estate tax. An effectively developed succession plan provides for a smooth transition in management and ownership with a minimum of transfer taxes.

Gillis (2012) defines the 10 steps to successful family business succession from the predecessor to his successor. One of these key points is also taxes and legal form of the business. Author emphasize that the choice of the legal form can be the decisive factor for the optimal timing of the ownership transfer and the business tax burden. Walny (2012) invites the family business owners to well-timed transfer of their businesses, because if they fail it can be according to author "targadeddon" for their business.

Research design and methodology

In order to achieve the defined aims of the research were used logical methods and comparasion method. For the purposes of the research was used the legislation valid to 1st January 2016. In connection to the fact it is also necessary to mention that, due to the repeal of Act No. 357/1992 Coll., on inheritance tax, gift tax and real estate transfer tax, which entered into force from 1st January 2014, there were covered interitance tax and gift tax to the Act No. 586/1992 Coll., on income tax.
The comparison method was used in the research especially for the purpose of comparison the tax effects of different ways of ownership transfer in the process of family business succession. For the purpose to make possible to compare the tax effects of various types of family business succession, it was first necessary to define the criteria that has to be submitted. The selected criteria, which were tested in the research, are following: legislation, taxpayer, object of taxation, tax base, tax rate, tax calculation and tax exemptions. The selected criteria were further divided for better orientation in the issue into three main areas (table 1).

Table 1: The main areas of selected criterias

Tested areas	General information	Calculation	Others
Selected criterias	Legislation Taxpayer Object of taxation	Tax base Tax rate Tax calculation	Tax exemptions

Source: authors

Results

In the framework of the research the main attention was focused on a comparison of the tax effects of different ways of the transmission ownership in family businesses succession in the Czech Republic.

The current legislation of the Czech Republic allows the conversion in following ways, namely: purchase, donation or other agreement, inheritance, decision of a state authority or under other circumstances prescribed by law. The results of the research are summarized in table 2.

Table 2: Tax effects of different family business succession forms

Areas	Selected criterias	Inheritance	Donation or Purchase	Real estate transfer
General information	Legislation	Act No. 586/1992 Coll., income tax	Act No. 586/1992 Coll., income tax	The legal measures of the Senate No. 340/2013 Coll., on tax of the acquisition immovable property
	Taxpayer	The heir (natural person or legal person), who acquirer the gratuitous income.	Natural persons, legal persons	The transferor of the real estate ownership; acquirer of the ownership
	Object of taxation	The natural persons: Incomes from employment, incomes from entrepreneurship, incomes from capital property, incomes from rental and other incomes. The legal persons: incomes from all the activities and from the loading with all assets.	The natural persons: Incomes from employment, incomes from entrepreneurship, incomes from capital property, incomes from rental and other incomes. The legal persons: incomes from all the activities and from the loading with all assets.	The paid acquiring real estate ownership, that is: parts of the grounds, building, a part of engeneering net or civil engeneering unit on the area of the Czech Republic, law construction by grounds on the area of tze Czech Republic, a co-owner share on the real estate.
Calculation	Tax base	The natural persons: the amount by which the taxpayer´s incomes exceed the expenses to achieve, maintain, and provide incomes* The legal persons: The difference between incomes excesses the expenditure. In the case of a taxpayer which is an accounting unit, it is a difference between revenue and costs, which must be further modified according to the Income Tax Act.	The natural persons: The amount by which the taxpayer´s incomes exceed the expenses to achieve, maintain, and provide incomes.* The legal persons: The difference between incomes excesses the expenditure. In the case of a taxpayer which is an accounting unit, it is a difference between revenue and costs, which must be further modified according to the Income Tax Act.	The acquisition value reduced by the accepted expenditure.
	Tax rate	The natural persons: 15 % of the tax base** The legal persons: 19 % of the tax base.	The natural persons: 15 % of the tax base The legal persons: 19 % of the tax base.	4 % of the tax base
	Tax calculation	The natural persons: Tax base x tax rate*** The legal persons: a modified tax base x tax rate.	The natural persons: Tax base x tax rate *** The natural persons: a modified tax base x tax rate	Tax base x tax rate

Others	Tax exemptions	The natural persons: § 4a paragraph 1 (a) Income Tax Act – the gratuitous income obtained from the inheritance or in disposition. The legal persons (business)*: § 19b paragraph 1 (a) Income Tax Act – the gratuitous income obtained from the inheritance or from the disposition.	According to § 10 paragraph 3 (d) Income Tax Act are tax exempt the gratuitous incomes from a relative in the straight line and from the indirect line**** In case of purchase: According to § 4 exemption from income tax is based on the time test. *****	The exemption can be used for new buildings and for units in compliance with the conditions.

Source: authors

*(Note: * if it is not in § 6 to § 10 otherwise specified;** the solidarity increase of tax amount is 7 % of the positive difference between the sum of incomes of the partial tax base from § 6 and partial tax base from § 7 of Income Tax Act; ***in the calculation of the final tax liability may still enter the so-called solidarity tax increase defined in § 16a of Income Tax Act; **** in terms it is sibling, uncle, aunt, nephew or niece, husband/wife, a child of spouse, the parents of spouse or husband´s / wife´s parents. Also from a person, whom the taxpayer lived for at least one year before getting the gratuitous income in the common household and for this reason he took care or was refrred to this person.; *****.* If it is filled with determined time by law, income from the purchase of movable or immovable property is exempt from tax.)

For better understanding of the research results there is added an elementary case study (table 3). The case study is focused on a self-employed person (a predecessor) passing his entrepreneurship to his descendants (a successor). The case study is oriented especially on the issue of the gratuitous transfer in family business and its tax effects. It is important to mention that the case studies come under the Income Tax Act competence since 1st January 2014.

Table 3: A case study on tax effects of family business succession

A case study	Tax effects	Notes
A self-employed person (a predecessor) passes the family business (as whole) to his son (a successor).	According to the Income Tax Act the gratuitous incomes obtained from the transfer of assets is not the object of the tax from the perspective of both persons (a predecessor and a successor) participating in the family business succession process.	The self-employed person (a predecessor) provided his business according to self-employed authorization. The son (a successor), who do not provide a business activities, has to gain his own self-employed authorization to provide further running of the business according to Act No. 455/1991 Coll., on trades.
A self-employed person (a predecessor) passes the family business to his two sons (sucessors).	For the both sucessors it is not possible to use the exemption of other gratuitous incomes from a relative placed in § 10 paragraph 3 of Income Tax Act. The gratuitous incomes in this case belongs to the cathegory of *„Incomes of separate activity“* placed in § 7 Income Tax Act, where the exemption of gratuitous incomes can not be used.	The both sucessors have their own businesses (in the legal form of self-employed persons) and for the Income Tax purpose lead the taxation evidence.

Source: authors

Discussion and conclusion

Family business succession represents a very large and complex issue. Authors across the approaches agree that transition ownership from one generation to the next generation is a difficult process, which has a whole range of incommutable specifics. Many authors also points to the fact that define a universal solution are not possible, because each process of succession is specific. The issue of family business succession is nowadays very current in the Czech Republic, because a large part of entrepreneurs that launched their business after the Velvet Revolution in 1989, has (or is fast approaching) retirement age and is forced to deal with the selection of the suitable successor. Selection of a suitable successor is absolutely crucial and must ensure further maintaining of the often successfully running business. The most so far realized research deals with the comparion of the selection of a suitable successor among certain groups. The part of authors (Wang, 2010; Koffi et al 2014a; Koffi et al, 2014b) compares, whether it is more appropriate as the successor to a man of woman, or whether it may struggle to post a successor between siblings put the running of the family business in danger (Miller, 1998; Avloniti et al, 2014)

Based on an extensive literature research, it was found out that in family business succession, the tax effects of this significant change is neglected and only a few authors (Dascher and Jens, 1999; Tralka, 2003; White et al, 2004; Giarmarco and Grassi, 2008; Giarmarco, 2012; Walny 2012; Gillis, 2012) pay attention to the issue. In the framework of the research was thoroughly explored taxation of different family business succession forms and it tax effects according to the legislation of the Czech Republic valid to 1st January 2016.

To obtain the results was necessary to define criteria, which were tested in the currently valid legislation. The comparison method was used for the purpose of the research.

The findings of the research have highlighted the specific area of the family business taxation and tax effects of different forms of family business succession, which is according to authors nowadays the main challenge in the family business succession process in the Czech Republic. The research findings show a significant impact of the currently valid legislation on the tax liability of family businesses in the succession process. The further research will be oriented on the taxation specifics of family businesses operating in the Czech Republic. The attention will be paid especialy to self-employed persons, different types of legal persons (allowed by the Czech legislation) and a copmetly new institute *"family factory"* defined by the new Civil code.

Abstract

Globally, e-learning has become the fastest growing sub-sector of the global educational market, as seen in the US market, because the demand for post-secondary education is increasing. Concurrently, the demand for post-secondary education is increasing because employment opportunities are decreasing. Most higher learning institutions implemented e-learning either as blended learning or as online learning services. Against this background, this study was undertaken to examine the relationship between the instructor's characteristics, university's support, system quality, information quality and service quality with the motivation to learn. Adopting the survey research method involving 250 respondents in a university setting, the study found that all hypotheses are supported.

Keywords: e-learning, instructor's characteristics, university's support, system quality, information quality and service quality

1.0 Introduction

In Malaysia, e-learning is no longer a new phenomenon, but it has not ceased to be a hot topic either (Adora et al., 2012). E-learning has been integrated into university courses as a component of the IT explosion and in fact, IT is the engine that drives the e-learning revolution (Selim, 2007). Therefore, this phenomenon has been occurring for about a decade, since the economic transition toward a knowledge-based economy. The implications of a knowledge-based economy are closely related to the roles of knowledge itself, as well as technology, which contributes to economic growth. Adora et al. (2012) added that a knowledge-based economy focuses on the development of human capital as the major contributor to a holistic development. Consequently, knowledge-intensive service sectors, such as higher learning institutions, incur heavy pressure to support this new environment. However, using technology in disseminating intensive information and knowledge, it will help sustain and accelerate the economic growth as well as support the pressure they face. In fact, this paradigm shift brought a new method in education. Thus, e-learning could be one of the new methods for institutions of higher learning to deliver their services to society, in which there is an extreme demand for knowledge. Most higher learning institutions implemented e-learning either as blended learning or as online learning services. Universiti Teknologi MARA (UiTM) for example, takes part in the implementation of e-learning with the existing i-Learn Center (i-LeC) as a supportive role (Nursyahidah et.al ,2012). Currently, i-LeC has formally launched the i-Learn Portal as a medium for e-learning, hoping it could be the solution for the growth of the student population in the university

within the time given and for the promotion of lifelong learning by taking advantage of the technological opportunity (Adora et al., 2012). The implementation of e-learning at UiTM was intended to provide more effective learning methods, as well as to increase learning motivation among learners through interactive learning styles.

In relation to the use of e-learning in Malaysian higher education, Adora et al. (2012) opined that e-learning could be the solution that caters to the growth of the student population with a variety of courses in multiple disciplines at various geographical locations. E-learning could also be a solution for the promotion of lifelong learning by taking advantage of the technological opportunity. Apparently, e-learning is an attractive alternative for this problem, which requires more classrooms at institutions with the prohibitive costs of building new facilities. Besides providing financial benefits, many higher learning institutions in Malaysia implemented e-learning because they believe in its effectiveness as an alternative learning approach (Maslim Masrom, 2008).

Despite the significant results and financial benefits that the adoption of e-learning provides for organizations, educational institutions still face significant challenges in ensuring that this technology is satisfactory and digestible for learners (Zaharias, 2008). In fact, a bundle of problems is associated with e-learning adoption, which either come from learners, instructors, systems, or management. According to Borotis, Zaharias, and Poulmenakou (2008), the main problem associated with e-learning adoption is the dropout rate of e-learning courses among learners, which fundamentally affected frustrated and non-motivated learners toward the e-learning system. This problem might have arisen because it is difficult to direct learners' attention to using the e-learning system due to human resistance, in which it is able to create unnecessary barriers for learners to complete the course (Ramakrisnan et al., 2012, Nurhizam (2007).

Therefore, poor quality of the e-learning system and the inappropriate use of technology also contributed to the poor usability of e-learning courses. The issue here is due to the poor usability of e-learning systems and ways to motivate learners as well as support them with a high quality of teaching. According to Zakariah et al. (2012), without making learners understand what technology is and how to use it to make them more comfortable with using it, it is difficult to create a positive learning experience that can motivate them to learn more. Thus, it is important to understand the factors that are embedded within e-learning that encourage learners to interact with the system and resulted in effective learning. That is why many researchers carried out a study of the critical success factors of e-learning in order to measure the success components of e-learning. Even though there are large numbers of literature on e-learning critical success factors, however, no systematic work exists on characterizing a collective set of vital factors for implementing successful e-learning environments, which contributes to the difficulties in identifying which factor is more important. Hence, identifying these vital factors is important in order to encourage learner's motivation to learn, as well as the factor playing a key role in the success of e-learning. This study seeks to answer the following research questions:

- Is there a relationship between the learner's characteristics and the motivation to learn?
- Is there a relationship between the instructor's characteristics and the motivation to learn?
- Is there a relationship between the university's support and the motivation to learn?
- Is there a relationship between system quality and the motivation to learn?
- Is there a relationship between information quality and the motivation to learn?
- Is there a relationship between service quality and the motivation to learn?

2.0 LITERATURE REVIEW

E-learning

Several definitions of e-learning have been discussed throughout the literature. Haron et al. (2012) stated that Agboola (2005) confines the notion of e-learning to using the computer and Internet technology to disseminate knowledge to learners effectively and to enhance the performances of both

the teacher and the learner by utilizing information and communication technology (ICT) for the purpose of instructional delivery. Therefore, according to Nor Zalina et al. (2012), e-learning is defined as the teaching and learning the approach that uses network technology as an important medium to support conventional class activities. In general, e-learning can be concluded as technological use in learning activities to deliver fast and reliable services.

Learners' characteristics

Learners may perceive the e-learning system differently. Normally, it depends on their characteristics. Bhuasiri et al. (2012) mentioned that Volery and Lord (2000) indicated that there are various learners' characteristics that may influence e-learning system adoption and usabilities, such as computer self-efficacy, Internet self-efficacy, computer experience, Internet experience, computer anxiety, and attitudes towards the e-learning system itself.

Instructor's characteristics

According to Bhuasiri et al. (2012), Webster and Hackley (1997) stated that instructor's characteristics refer to the instructor's attitudes toward technology, teaching styles, and technology control, influencing learning outcomes. In addition, Bhuasiri et al. (2012) stressed that many of the past studies showed that relevant instructor characteristics include timely responses, self-efficacy, technology control, a focus on interaction through the system with learners, attitudes toward e-learning, attitudes toward students, distributive fairness, procedural fairness, and interaction fairness. These set of characteristics seem critical for instructors to ensure the effectiveness of e-learning system.

University's support

The university's support is also one of the critical factors of e-learning mentioned in past studies. According to Selim (2007), the university's support refers to the items that were related to any kind of e-learning initiatives available, including library services, the help desk, computer labs and facilities, and the training center. All these initiatives would enhance the users' satisfaction when using the systems.

From the previous study, Hassanzadeh et al. (2012) concluded that system quality refers to the performance of the system in terms of reliability, ease of use, and other indicators of systems. Bhuasiri et al. (2012) argued that system quality relates to a learner's belief about e-learning performance characteristics. Therefore, DeLone and McLean (2003) added that system quality could be measured by functionality, ease of use, reliability, flexibility, data quality, portability, integration, and importance. System quality would enhance learning motivation because the performance of the system would encourage learners to participate in the learning system as well as contribute to learning effectiveness.

Information quality

Information quality is reflected in the well-designed course, curriculum, and learning materials that facilitate the learning process. Information quality can be defined as the accuracy, completeness, ease of understanding, and relevance of online course materials (Bhuasiri et al., 2012). DeLone and McLean (2003) stated that information quality could be measured in terms of accuracy, timeliness, completeness, relevance, and consistency.

Service Quality

Bhuasiri et al. (2012) defined service quality in e-learning research as the overall support delivered by the e-learning system to the learners who use the system. Service quality is important because it influences users' satisfaction. Through providing support, management, training, equipment, facilities, accessibility, and delivery methods, users' needs could be fulfilled and they would be able

to get positive feedback from their users. Therefore, in terms of measurement, DeLone and McLean (2003) proposed that the five dimensions of SERVQUAL, which are tangibles, reliability, responsiveness, assurance, and empathy, could measure service quality.

Table 1: Summary of the previous study

Author	Aim of study	Research Method	Main Findings
Nurhizam Safie (2007)	To investigate the relationship between usability attributes and motivation to learn	Quantitative	Ten new usability attributes representing as motivation to learn construct which grouped into three categories which is web usability, pedagogical usability and universal usability
Hassanzadeh, Kanaani & Elahi (2012)	To survey and present a model for measuring success of e-learning systems	Quantitative	Technical system quality, education system quality, content and information quality, service quality, user satisfaction, intention to use, user loyalty to system, benefits of using system and goals achievement, are suitable component for measuring e learning systems success.
Bhuasirri et al. (2012)	To identify the critical success factors that influence the acceptance of e-learning systems	Quantitative – Delphi methods	Results reveal six dimensions and 20 critical success factors (CSFs). Technology awareness, motivation and changing learners' behavior are prerequisites for successful e-learning implementations.
Hassan M. Selim (2007)	To specify e-learning critical success factors (CSFs) as perceived by university students.	Quantitative – survey instruments	Results revealed 8 categories of e-learning CSFs, each included several critical e-learning acceptance and success measures
Othman Zainon, Maslin Masrom & Rosdina Rahiman (2008)	To determine the critical success factors with regards to the acceptance of e-learning from the students' viewpoints.	Quantitative – survey instruments	Instructor characteristics factor is the most critical factor in e-learning
Zaharias (2008)	To identify the usability constructs with instructional design which influence motivation to learn	Interpretation of Keller's ARCS model	Twelve new usability parameter were identified which influence motivation to learn

Table 2: Summary of main theories and model applied in past studies

Theories/ Model	Core constructs
DeLone & McLean IS Success Model (DMISSM)	System quality Information quality Organizational impacts
E-learning Critical Success Factors (CSFs) Model	Learner's characteristic Innstructors' characteristic Extrinsic motivation System dimensions Environemnet dimensions
Measuring E-Learning System Success (MELSS) Model	Technical system quality Educational system quality Content and information quality Service quality User satisfaction Intention to use Use of the system Loyalty to system Benefit of using e-learnig systems Goal achievement
Hierarchical E-learning Critical Success (CSFs) Model	Learner's characteristics Instructors' characteristics Institution and service quality Insfrastructure and system quality Course and information quality Extrinsic motivation
Technology Acceptance Model (TAM)	Perceived usefulness Perceived ease of use Subjective norm
Confirmatory Factor Model	Learner's characteristics Instructors' characteristics Technology support University's supports
Motivational Theory	Intrisic motivation Extrinsic motivation

Theoretical Review

As this research is concerned with clarifying the most critical factors that could be influence a learner's *motivation to learn* when using e-learning system, it is important to examine the models and theories used in the e-learning literatures. The DeLone and McLean IS Success Model (DMISM) have received the most attention by researchers in justification of e-learning critical success factors. The construct of this model is based on system quality which measures technical success, information quality in term of accuracy, timeliness, reliability, format etc and organization impact which measures effectiveness success in the context of e-learning environment. Most of authors argued that the success of using technology was derived from information and system quality (Bhuasiri, et al. (2012), Hassanzadeh, et al. (2012) & Selim (2007)). Likewise, Hassanzadeh, et al. (2012) revised this model of Delone and McLean for measuring success of e-learning systems and come out with new model called as Measuring e-Learning System Success (MELSS) Model. Otherwise, Technology Acceptance Model (TAM) which is adopted from Theory of Reasoned Action (TRA) also discussed in several literatures. Technology acceptance model were employed by several authors to support their proposed e-learning Critical Success Factor (CSFs) Model.

In relation to motivation to learn, it is identifies that most of researcher were used Motivation Theory in their study. This theory stated that there are two types of motivation which is intrinsic

and extrinsic. Bhuasiri, et al. (2012) claimed that both intrinsic and extrinsic motivation had a significant positive effect on student self-efficacy. Likewise, Armenterous, et al. (2013) agreed with this point. Otherwise, he also makes the point that both intrinsic and extrinsic motivation can be one other kind of factors which influence users' intention to use the systems. Moreover, Nurhizam (2007) and Zaharias (2008) in their study relied on Keller's Arcs Model of Motivational Design (1983) in order to analyze and interpret motivation to learn constructs. From this model there are four constructs such as attention, relevance, confidence and satisfaction were used in their study.

Theoretical Framework

The proposed research framework for this study was constructed from an adaptation of four key models as been discussed in the theoretical review which is DeLone and McLean IS Success Model (DMISM), e-Learning Critical Success Factors (CSF) Model, Measuring E-Learning System Success (MELSS) Model and Motivational Theory.

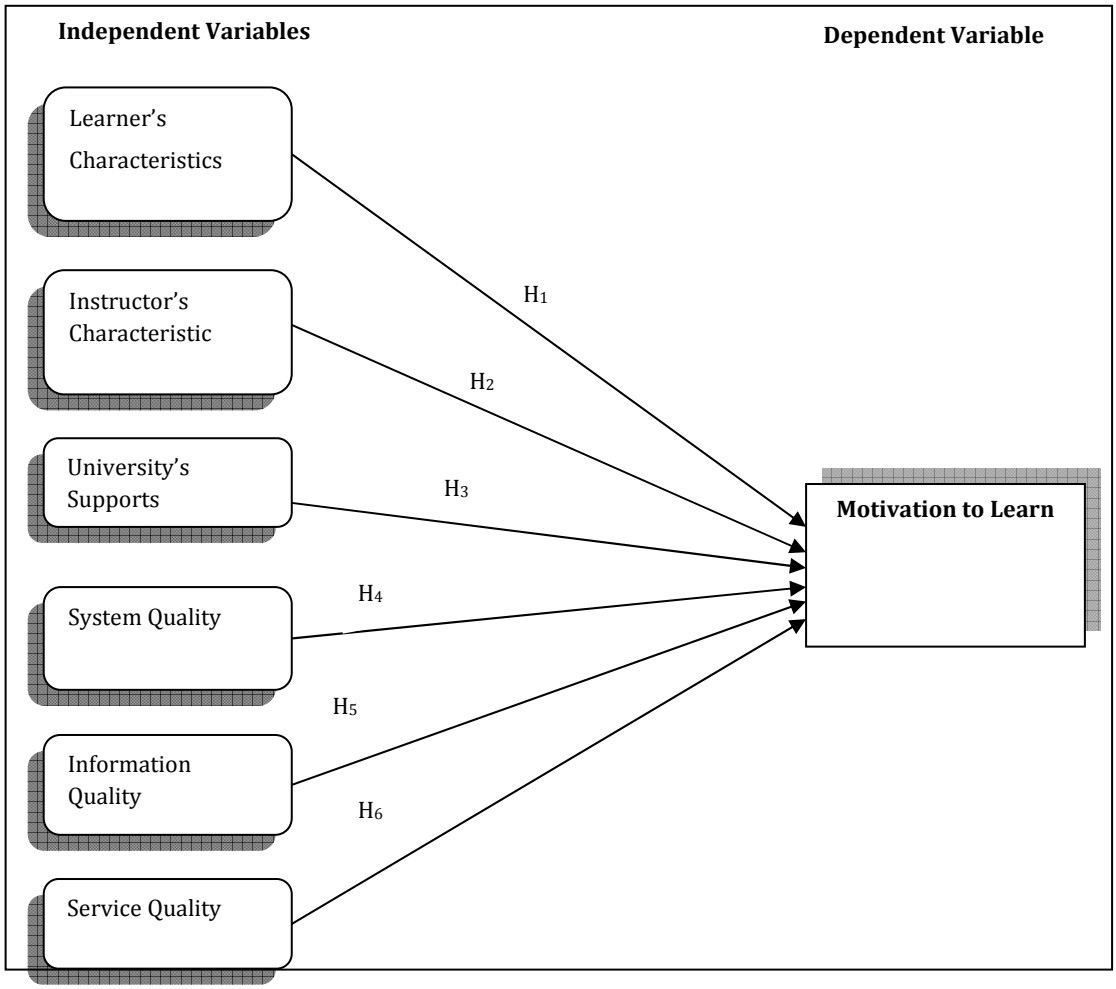

Table 3: Summary of e-learning critical success factors (CSFs)

Past studies	E-learning critical success factors (CSFs)
Hassan M. Selim (2007); Bhuasiri, et al. (2012); Othman Zainon, Maslin Masrom & Rosdina Rahiman (2008);	Learner's characteristic
Hassan M. Selim (2007); Bhuasiri, et al. (2012); Lee, et al. (2009); Othman Zainon, Maslin Masrom & Rosdina Rahiman (2008);	Instructor's characteristic
Hassan M. Selim (2007); Bhuasiri, et al. (2012);	University's support
Hassan M. Selim (2007); Bhuasiri, et al. (2012); Hassanzadeh, et al. (2012)	System quality
Bhuasiri, et al. (2012); Hassanzadeh, et al. (2012);	Information quality
Bhuasiri, et al. (2012); Lee, et al. (2009); Hassanzadeh, et al. (2012);	Service quality

Based on the above, this study proposed the following hypothesis:

H_1: There is a positive relationship between learner's characteristics with motivation to learn
H_2: There is a positive relationship between instructor's characteristics with motivation to learn
H_3: There is a positive relationship between university's supports with motivation to learn
H_4: There is a positive relationship between system quality with motivation to learn
H_5: There is a positive relationship between information quality with motivation to learn
H_6: There is a positive relationship between service quality with motivation to learn

3.0 Research Methodology

The research process which involves several steps in the planning for actual study which include 1) problem identification; 2) theoretical framework; 3)_hypothesis formulation; 4) data collection;5) data analysis and interpretation, deduction;6) report writing and report documentation. 250 questionnaires were distributed . Respondents were selected based on their usage toward i-Learn Portal for their studies. Only 203 questionnaires were returned and analysed.

Research Instrument

Questionnaires will be used as the research instrument in gathering data for this study that adopted from the previous studies on CSF and motivation to learn. A questionnaire is a pre-formulated written set of questions to which respondents record their answers. It is an efficient manner of obtaining data due to its nature in that it can be easily distributed and measured. Furthermore, the data collected have the highest probability of being valid, as respondents can take more time to answer the questions at their convenience. As a result, they can provide the best information to the researcher. In this study, questionnaires will be distributed to the respondents. The questionnaire used will obtain data on:

- Demographic information of the respondents (using a nominal scale of measurement).
- E-learning critical success factors by the respondents (using a 10-point scale ranging from 1 as strongly disagree to 10 as strongly agree).

- Motivation to learn among the respondents (using a 10-point scale ranging from 1 as strongly disagree to 10 as strongly agree).

4.0 Findings

The Reliability Analysis for the Measuring Variables

Table 4 provided the values of Cronbach's alpha for all tested variables were higher than 0.7. It was important to note here that all reliability measures have achieved the accepted "desirable" level of 0.80 for social science research as recommended by (Money & Turner, 2004).

Table 4: Reliability Statistics for Questionnaire Items

Variables	Number of items in a component	Cronbach's Alpha
Learners' Characteristics	7	**0.802**
Instructors' Characteristics	6	**0.927**
University Support	7	**0.884**
System Quality	5	**0.938**
Information Quality	6	**0.896**
Service Quality	6	**0.962**
Motivation to Learn	6	**0.937**

The Mean Analysis for the Measuring Variables

The next step was to transform the individual score of independent variables into its individual mean for preferred factor comparison by the respondents. The same procedure repeated for other variables respectively. Table 5 illustrated the mean scores and standard deviations for the measured variables. It was found that System Quality variable had the highest score for the response, with mean = 7.4158 and standard deviation = 1.62595 which indicated the most preferred factor among the others to motivate e-learning among the respondents.

Table 5: Mean Comparisons for the Measuring Variables

Variables	Mean	Standard Deviation (SD)
Learners' Characteristics	7.2126	1.18592
Instructors' Characteristics	6.6626	1.74923
University Support	6.8331	1.60148
System Quality	**7.4158**	**1.62595**
Information Quality	7.1502	1.58114
Service Quality	6.5619	1.77660

The Analysis to Determine the Normality of the Data

After obtaining the mean scores for each component, the researcher must show that the distribution of these data also did not depart from normality. As stated earlier, one of the measures which reflected the distribution of data was skewness. The measure of skewness between -1.0 to 1.0 indicated the data did not depart from normality. Hence, the parametric statistical analysis could be employed.

Table 6: The Measure of Skewness of the Data

Variables in the Model	min	max	skewness	kurtosis
Learners' Characteristics	3.71	10.00	**-0.137**	0.120
Instructors' Characteristics	1.83	10.00	**-0.311**	-0.436
University Support	2.71	10.00	**-0.428**	-0.411
System Quality	2.20	10.00	**-0.735**	0.686
Information Quality	1.83	10.00	**-0.559**	0.287
Service Quality	1.00	10.00	**-0.375**	0.078
Motivation to Learn	1.17	10.00	**-0.618**	0.673

Since all measures for the skewness were closer to 0.0 and within the range between -1.0 to 1.0 the study concluded that the distribution of data was almost symmetry or bell-shaped. The bell-shaped distribution indicated the data was normally distributed. Hence, the data obtained in the study fulfill the required assumption for employing the parametric statistical analysis that data came from a normal distribution. Among the parametric statistical analyses that could be employed were t-test and F-test depending on the hypothesis test proposed for the study.

Parametric Statistical Analysis

Hypothesis 1

Ha1 : There is a positive relationship between learner's characteristics and motivation to learn.

Table 7: Correlations Test for learner's characteristics and motivation to learn.

		LEARNERS_ CHARACTERISTICS	MOTIVATION_TO_LEARN
LEARNER'S_CHARACTERISTICS	Pearson Correlation	1	**0.580****
	Sig. (2-tailed)		**0.000**
	N	203	203
MOTIVATION_TO_LEARN	Pearson Correlation	**0.580****	1
	Sig. (2-tailed)	**0.000**	
	N	203	203

**. Correlation is significant at the 0.01 level (2-tailed).

The Pearson correlations test was performed to determine if there was a significance relationship between learner's characteristics and motivation to learn (see Table 7). Learner's characteristics were positively correlated with motivation to learn ($p < 0.01$, $r = 0.580$) but moderate. Hence, the results revealed that there was a significance positive linear relationship between variables and alternative hypothesis was supported. This conclusion was made at the significance level, $\propto = .05$ (5%) or confidence level (95%).

Hypothesis 2

Ha2 : There is a positive relationship between instructor's characteristics and motivation to learn.

From Table 8, it was found that instructor's characteristics were highly correlated with motivation to learn ($p < 0.01$, $r = 0.706$) and null hypothesis was rejected. Hence, the results revealed that there was

a significance positive linear relationship between variables. This conclusion was made at the significance level, ∝ = .05 (5%) or confidence level (95%).

Table 8: Correlations Test for Instructor's Characteristics with Motivation to Learn

		INSTRUCTOR_ CHARACTERISTICS	MOTIVATION_TO_LEARN
INSTRUCTOR'S_CHARACTERISTICS	Pearson Correlation	1	**0.706****
	Sig. (2-tailed)		**0.000**

	Sig. (2-tailed)	**0.000**	
	N	203	203

**. Correlation is significant at the 0.01 level (2-tailed).

Hypothesis 3

Ha3 : There is a positive relationship between university support and motivation to learn.

A Pearson correlation analysis performed to test the relationships among tested variables (see Table 9). The correlations between university support with motivation to learn ($p < 0.01$, $r = 0.726$) were also high and positive at the .05 (5%) level of significance. Therefore, alternative hypothesis was supported.

Table 9: Correlations Test for University Support with Motivation to Learn

		UNIVERSITY_SUPPORT	MOTIVATION_TO_LEARN
UNIVERSITY_SUPPORT	Pearson Correlation	1	**0.726****
	Sig. (2-tailed)		**0.000**

	Sig. (2-tailed)	**0.000**	
	N	202	203

**. Correlation is significant at the 0.01 level (2-tailed).

Hypothesis 4

Ha4 : There is a positive relationship between system quality and motivation to learn.

As demonstrated in Table 10, system quality was positively correlated with motivation to learn ($p < 0.01$, $r = 0.656$) but moderate. Hence, the results revealed that there was a significance positive linear relationship between variables at the .05 (5%) level of significance and null hypothesis was rejected.

Table 10: Correlations Test for System Quality with Motivation to Learn

		SYSTEM_QUALITY	MOTIVATION_TO_LEARN
SYSTEM_QUALITY	Pearson Correlation	1	**0.656****
	Sig. (2-tailed)		**0.000**
	N	202	202

	Sig. (2-tailed)	**0.000**	
	N	202	203

**. Correlation is significant at the 0.01 level (2-tailed).

Hypothesis 5

Ha5 : There is a positive relationship between information quality and motivation to learn.

A Pearson correlation analysis conducted to test the hypotheses. Table 11 illustrates positive and significant relationships between information quality and motivation to learn. It was indicated that the correlations between the variable were high and positive ($p < 0.01$, $r = 0.760$) at the significance level, $\propto = .05$ (5%) or confidence level (95%) and alternative hypothesis was failed to be rejected.

Table 11: Correlations Test for Information Quality with Motivation to Learn

		INFORMATION_QUALITY	MOTIVATION_TO_LEARN
INFORMATION_QUALITY	Pearson Correlation	1	**0.760****
	Sig. (2-tailed)		**0.000**
	N	202	202
MOTIVATION_TO_LEARN	Pearson Correlation	**0.760****	1
	Sig. (2-tailed)	**0.000**	
	N	202	203

**. Correlation is significant at the 0.01 level (2-tailed).

Hypothesis 6

Ha6 : There is a positive relationship between service quality and motivation to learn.

The highest positive relationship was found between the service quality and motivation to learn. As showed in Table 12, the results revealed that there was a significance positive linear relationship between variables ($p < 0.01$, $r = 0.767$) and null hypothesis was rejected. This conclusion was made at the significance level, $\propto = .05$ (5%) or confidence level (95%).

Table 12: Correlations Test for Service Quality with Motivation to Learn

		SERVICE_QUALITY	MOTIVATION_TO_LEARN

	Sig. (2-tailed)	**0.000**	
	N	202	203

**. Correlation is significant at the 0.01 level (2-tailed).

Summary of Hypotheses Test Results

No	Hypothesis		Data Analysis Technique	Result
1	**Ha1**	There is a positive relationship between learner's characteristics and motivation to learn.	Pearson correlations test	**Supported**
2	**Ha2**	There is a positive relationship between instructor's characteristics and motivation to learn.	Pearson correlations test	**Supported**
3	**Ha3**	There is a positive relationship between university support and motivation to learn.	Pearson correlations test	**Supported**
4	**Ha4**	There is a positive relationship between system quality and motivation to learn.	Pearson correlations test	**Supported**
5	**Ha5**	There is a positive relationship between information quality and motivation to learn.	Pearson correlations test	**Supported**
6	**Ha6**	There is a positive relationship between service quality and motivation to learn.	Pearson correlations test	**Supported**

5.0 Discussion

1. The positive relationship between learner's characteristics and motivation to learn.

The finding was consistent with the previous study by Selim (2007) who agreed that identifying the learner's characteristics is important to the successful of e-learning acceptance. Volery and Lord (2000) supported that there are various learners' characteristics that may influence e-learning system adoption and usabilities, such as computer self-efficacy, Internet self-efficacy, computer experience, Internet experience, computer anxiety, and attitudes towards the e-learning system itself. The result also was agreed by Lim, Morris and Yoon (2006) which revealed that learner's motivation to study was affected by characteristics of learner such as demographic information, learning preferences and technical skills. Therefore, another study by Lim and Kim (2003) stated that learner's characteristics such as demographic information, computer experience, and previous online learning experience may influence online learning performance and satisfaction as well promote online learning motivation among learners.

Moreover, Olasina (2012) study also found that students with IT knowledge, technical skill, and computer experience were motivated to use e-learning. When relating to learning motivation, Chua and Don (2013) mentioned that motivation is the most important driving force to explain online students' ability to pass exams that are the only variable that shows a direct, positive and significant effect on students' achievement. Shih (2013) et al. confirmed that self-development and social contact are the two significant variables among motivation factors to predict online learning satisfaction. From the findings, it was found that more than 50% of respondents have good knowledge in using the i-Learn portal and are motivated in their learning process.

2. ***The positive relationship between instructor's characteristics and motivation to learn.***
Ozkan and Koseler (2009) stated that learners' attitudes and instructor's quality are the critical predictors for learners' satisfaction. Specifically, Bhuasiri et al. (2012) explained that instructor's characteristic measures in term of the timely response, self-efficacy, technology control, focus on interaction, attitude toward students and interaction fairness are the critical determinants of e-learning success. It was found that lecturers who taught Information Management courses also have good IT knowledge and skills and delivered the lecture contents using ICT tools during the classes. This was agreed by Webster and Hackley (1997) that instructor's characteristics refer to the instructor's attitudes toward technology, teaching styles, and technology control is influencing learning outcomes.

3. ***The positive relationship between university support and motivation to learn.***
Bhuasiri et al. (2012) also agreed that providing support, equipment accessibility, and training by the university are important issues for e-learning acceptance. Similarly, Lee (2008) found that providing computer support and training to learners by the universities are strongly influenced a learner's perceived ease of use and usefulness of the system. Changchit (2007) further supported that learners' on-line learning satisfaction is affected by factors like learners' technology acceptance behaviors, quality of institutional support, academic environment and instructional interaction. Wagner et al. (2006) confirmed that technological infrastructures placed in the institutions such as course management systems, technology equipped classrooms, sufficient bandwidth and adequate computer facilities for student use play a vital role on how effectiveness of e-learning offerings may be assessed and this may be effect the return on investments (ROI) of the institutions. It was found that most of Information Management core courses were taught in conductive computer laboratory provided by the university. Thus, to improve e-learning skills, before the semester begins, the students have to attend two i-Learn workshops organized by i-Learn trainers namely 'Go i-Learn Day' and 'Blended Learning'. The aim of 'Go i-Learn Day' is to meet the students and train them on how to use the portal while blended learning refers to courses that combine face-to-face classroom instruction and online instruction with reduced classroom contact hours containing a variety of learning activities with the use of technology, lecturer and peer interaction (Md Noh et al., 2012).

4. ***The positive relationship between system quality and motivation to learn.***
Maldonado et al. (2011) said that technology characteristics such as ease of use and effort expectancy should be considered for the students to be motivated to use the e-educational system. Bhuasiri et al. (2012) verified that system quality has a strong positive effect on learners' satisfaction. DeLone and McLean (2003) added that system quality would enhance learning motivation because the performance of the system. Otherwise, Hsiu and Su (2012) revealed that system functionality, response, and interactivity factors may influence student satisfaction and motivate them to continue in lifelong e-learning course

Bhuasiri et al. (2012) indicated that information quality has a strong positive effect toward learners' satisfaction because learner's satisfaction influences learning motivation. Then, DeLone and McLean (2003) defined that information quality could be measured in terms of accuracy, timeliness, completeness, relevance and consistency. Teo (2011) further described that the way in which e-learning course is delivered has affected the e-learners' perceptions toward their motivations.

5. ***The positive relationship between information quality and motivation to learn.***
Bhuasiri et al. (2012) indicated that information quality has a strong positive effect toward learners' satisfaction because learner's satisfaction influences learning motivation. Then, DeLone and McLean (2003) defined that information quality could be measured in terms of accuracy, timeliness, completeness, relevance and consistency. Teo (2011) further described that the way in which e-learning course is delivered has affected the e-learners' perceptions toward their motivations.

6. ***The positive relationship between service quality and motivation to learn.***
Law, et al. (2010) found that there is a positive relationship between motivation and performance among students taking computer programming courses in an e-

learning setting. In addition, Bhuasiri et al. (2012) stated that service quality is important because it influenced users' satisfaction from the positive feedback. Sun (2008) discovered that service quality measurement tools have been developed in e-learning environment in which the quality of e-learning teaching materials affected e-learners' satisfactions. Chen, Lee and Chen (2005) added that high-quality teaching materials motivate learners to use e-learning through the development of learner-centered teaching contents. For that purpose, an e-content project known as Subject Matter Experts (SME) was developed via i-Learn to promote knowledge sharing, content standardization, accessibility as well as to simplify learning process (Md Noh et al., 2012).

Conclusion

This study verified the factors for e-learning and the relationship with motivation to learn. These correlations are measured from the hypotheses tests and, therefore, supported the conceptual framework. Among these factors, service quality was found to be the highest significant correlated with motivation to learn while learner's characteristics were found to be the lowest significant correlated with motivation to learn. The system quality was identified as the most preferred determinant to motivate the students to use e-learning. It could be regarded that the e-learning has played the significant roles for motivating the students throughout their research and studies.

Acknowledgements

We would like to extend our deepest gratitude to Universiti Teknologi MARA (UiTM), for giving us the opportunities to conduct this research project.

Abstract

Young adults are exposed to extensive options of news media which available for free, fee based, printed or online. News media undergo drastic change and obviously has change the way young adults perceived and apply in their daily routines. In Malaysia, news media consumption among young adults is not new. It usually associated with conventional printed media such as newspaper. However, with the emerge of the information technology (IT) and high level of literate young adults, it is believe that there are other options adopted to be well informed. The study explored the everyday life information seeking (ELIS) of Malaysian young adults news media consumption. Overall, this research intends to further understand of the everyday life information seeking (ELIS) behavior of young adults, which include how they apply or seek information for personal development and growth. The study adopted survey research method and instrument used was self-administered questionnaire. The sample size suggested for the study is 335. Findings show that the young adults news consumption in Malaysia has change literally from printed towards digital platform. Schools and parents have started with subscription into e-news which can be accessed anywhere and at anytime.

Keywords: everyday life information seeking, young adults, news media consumption, news media contents , news media format/sources and value of news

1.0 Introduction

Young adults are exposed to extensive options of news media which available for free, fee based, printed or online. News media undergo drastic change and obviously has change the way young adults perceived and apply in their daily routines. Young adults are believed to read less printed newspaper compared with other age groups (Edmonds, Guskin, & Rosenstiel, 2011).

Most news experts assume young people have less interest in reading print newspapers and prefer to go for online news (Kaufhold, 2010). Therefore, it is widely phenomenal of news media to adopt online version to support their business, marketing strategy and advertisements. Thus, it is crucial for newspaper firms to involve and participate heavily in extensive news delivery platforms. They willing to invest and experiment latest trend of social media in order to catch and retain young readers' interest (Graybeal, 2011). Studies conducted by Chyi & Chang (2009) and De Waal, Schoenbach, & Lauf (2005) agreed that printed newspaper is most preferable option as people find it more useful, reliable, friendly and enjoyable compared to online version. Somehow, it shows printed newspaper has close relationship bound where user naturally able to feel and touch them. The Online Publishers Association (2004) survey produced the same opinion as well. . They willing to invest and experiment latest trend of social media in order to catch and retain young readers' interest (Graybeal, 2011). Studies conducted by Chyi & Chang (2009) and De Waal, Schoenbach, & Lauf (2005) agreed that printed newspaper is most preferable option as people find it more useful, reliable, friendly and enjoyable compared to online version. Somehow, it shows printed newspaper has close relationship

bound where user naturally able to feel and touch them. The Online Publishers Association (2004) survey produced the same opinion as well.

However, later on as technology takes place, the newspaper experts in the industry believed that young people is a trendsetter. Young people aged 18-24 also known as *digital natives* is likely to adapt the Web, social media, or mobile applications in their daily routines. This will affect news and information searching behavior simultaneously. It is therefore important to revise the trend toward online and print media among young readers' attitudes. The phenomenon of online news are easy acceptable by young people around the globe. Geographical, language and time are no longer considered as barrier. Facility such as tools and internet would be among small percentage for young reader not to get in touch with online news media. It is believed that, user with no internet and technology devices will eventually has one from various social media account. Thus, it has been a part of social life regardless of age, gender, race, religion and nationality. Where else, traditional printed media has been seen reducing its volume, size and content due to high cost but lower usage. However, the newspaper industry has served the world for years and contributed benefits in term of information and knowledge sharing. As to date, the industry has taken bold and aggressive approach to reach its users and clients. The changes are according to trend and users' preferred interest. Today newspapers are no longer plain and text oriented. It has been transformed into eye-capture images, courageous text and interesting typography to set the mood, feel and fresh look. They come in compact size and online version as well. On the bright sight, the study will help information provider to evaluate and consider youth preferences to access news. Ito (2008) found that social network sites and other supporting application tools have great impact of youth culture. Studies have shown that young adults and indeed the Generation Z appear to have a massive influence on the survival evolution of news delivery platforms. Thus, the situation today and the emergence of internet have largely shown that the conventional printed newspaper has less contact with young adults (Qayyum et al., 2010).

Besides than investigating local young adults 'adults' news media consumption, the study would able to produce real lifestyle of young adults in urban location of Malaysia. The study would eventually generate information behavior among young adults towards news consumption.

In Malaysia, news media consumption among young adults is not new. It usually associated with conventional printed media such as newspaper. However, with the emerge of the information technology (IT) and high level of literate young adults, it is believe that there are other options adopted to be well informed.

Qayyum et al., (2010) suggested that age divide would critically affect on behavior as maturity level increase their confidence and needs to explore different type of news media platforms. Technology has taken the place and introduce social networking using smart phones, tablets and laptops.

The study explored the everyday life information seeking (ELIS) of Malaysian young adults news media consumption. Overall, this research intends to further understand of the everyday life information seeking (ELIS) behavior of young adults, which include how they apply or seek information for personal development and growth. This study seeks to answer the following research questions:

(i) What are the news media consumption among young adults in Selangor?
(ii) What are the news media contents among these young adults ?
(iii) What are their preferred news media format/sources?

2.0 Literature Review

Preferences

Preference or reading preference is defined as reader's prior choice, favorite and most like reading matter from different range of formats namely books, magazines, books or newspaper. The

preferences could also range from genre, subject and author. The preference may influence by several factor such as lifestyle, psychological, background, interest and career development.

Interest

Freeman (2013) emphasized findings of her study that most Malaysian young adults prefer the internet as their main source of news. Additionally, their news interest mostly from news online, blogs and social media tools. They make active media choices particularly about the type of news and media they prefer to access.

News media

There are varieties of conventional media such as newspaper, books, magazines, radio and television have adopt new platform using digital media and blend harmoniously with interactive media and social network. The on-the-go phenomenon such as blogs, podcasts and social networks have proven to reach different walk of life and reduce geographical divide within users. It has enhances communication which incorporates digital productions, streaming media, typography and less complicated.

Young adults

According to The United Nations young adults are defined as persons between the ages of 15 and 24. The group is also refer as a heterogeneous group in regular development and the experience of 'being young' varies extremely across regions, culture and within countries. In Malaysia, youth are defined as person between ages of 18 and 25, while the Commonwealth's is between 15 and 29.

Everyday-life information seeking (ELIS)

The term ELIS pioneered by Savolainen (1995) to refer to the behavior, practice and habit of information seeking that people spend to adopt themselves in daily life or to solve problems indirectly. Savolainen also emphasized the practice much influenced by culture, background and lifestyle.

The Evolution of News Media

The newspaper industry worldwide started experimenting with online delivery in the mid-1990s when many newspapers launched electronic editions on the Web. Since then, newspapers have come in two distinct formats: online and in print. Newspaper companies once hoped that their dual product offerings would go hand in hand; however, the online edition has failed to generate sufficient revenue to make up for the deficiencies on the print side, as evidenced in the US newspaper crisis in 2009 (Karp, 2007)

Young adults and Everyday life information seeking (ELIS)

Today, ELIS has been practiced at early age to nurture them as efficient, independent and productive in future. The skill will assist them to make the maturation process easier for young people. Therefore, public and school libraries are in ideal positions for providing reliable information through collection, services and reading facilities. School and public libraries are equip with edutainment collection for teaching and learning process. Whilst, academic libraries would cater larger and professional information resources to fulfill their needs. However, there are also youth-centered researches exists to serve either the basic information-seeking behavior of teenagers, or reference and information services for young adults (Shenton & Dixon, 2004).

News Consumption among Young Adults

The Pew Research Center for the People and the Press (2010), mentioned about 46% of those over the age of 65 reported reading a print newspaper while those ages range 18-24, only 7 % consume

from printed newspaper. Consequently, the results have pointed the news consumption among young adults has existed before internet became the major medium. The behavior later been further investigated in 2011 study by the Pew Research Center's Internet & American Life Project. The survey concluded 94% of young adults in US spent most of the times browsing the internet to seek information and news. The environment most likely happened as the country is well equipped with technology and ICT facilities plus, the younger generation are exposed to employ internet in their daily lives.

Kaufhold (2010) suggested that 90% of survey results believed that young adults chose online news compared to print news. As technology takes place and Internet become necessity, news media industry hinting at the future of print newspapers would be no longer common information sources. Variety of news media available 24/7 via online has replace news consumption around the globe at great pace (Penenberg, 2004).

The technology trend believed has largely shaped the news industry now and future (Chyi & Lee, 2012). As a result, newspaper industry has reduced its volume and concern to invest more in digital online business. The significant transformation in the industry created added value for advertisement business as well. It created aggressive and strong market industry especially to penetrate young adults age group. This has been proven by a survey conducted by Graybeal (2011) which indicated that interactive web and digital media as main concern today. There were more research findings also widely accepted assumption that young people use the Internet to seek news and information.

On the other hand, Mindich (2005), disagreed oppose other research mentioned above regarding young adults preference to go news online. Young adults approach towards technology and internet are doubted to consume news and information. They are likely to browse entertainment, online shopping, online banking and games.

An important term initiated by Chyi (2009) referring to generation gap in news consumption is news fatigue. As likely to support the theory, Chyi emphasized news fatigue as the environment where young adults receive tones of news in extensive resources. The problem occur when young adults fail to differentiate the news credibility, accuracy and authenticity as news gone viral and anonymously. The situation created by the advances of internet, high-tech gadgets such as smart phones and technology savvy among young adults nowadays. The news delivery has shifted from paper based to wireless plus able to reach users just in seconds.

In Malaysia, young adults have spoken their preferences towards news media consumption. They opt to choose online media compared to printed media and entertainment would be their main interest in news searching. According to a research by Freeman (2013), the scenario in two universities show young adults spend most of their daily routine browsing internet either for academic purposes or personal interest topic. This behavior followed by Google as the most popular search engine nowadays. Additionally, young adults favor sports, crime news, famous celebrity or icon and latest events happening in their community.

Format Preference: Print vs. Online

Some of the studies found that printed newspaper are more preferable by young adults (Chyi & Chang, 2009; De Waal et al., 2005)

Despite the overwhelming acceptance of news online, essentially printed version still maintain its reputation and able to survive nowadays. For this reason, it can be seen that, news industry taken major transformation to blend printed and online packages. These may very useful for large organization, schools and libraries. Most specifically it helps to save space and environment friendly.

The Conceptual Framework for the study is shown in Figure 1 and the past studies that determine the variables of the study is in Table 1.

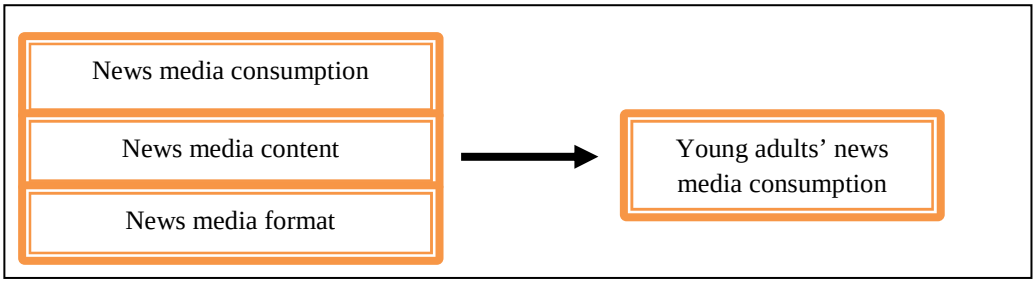

Figure 1: The Conceptual Framework

Table 1: Past Studies

Past studies	Young adults' news media consumption
The Pew Research Center for the People and the Press (2010), Kaufhold (2010), Penenberg (2004), Chyi & Lee (2012), Graybeal (2011), Mindich (2005), Chyi (2009), Freeman (2013).	News media consumption patterns
Kaufhold (2010), Penenberg (2004).	News media content
Chyi & Chang (2009; De Waal et al.(2005)	News media format

Dependent variable

Young adults news media consumption

Basically, the study would like to investigate the trend of news media consumption happening among young adults. Today, young adults are surrounded with the emergence of news media either via online or printed version. News industry been aggressive and all out to reach young adults interest as this group will shape future news media development respectively. At this age, conventional news media has ventured into online news in order to keep in track and maintain survival.

Independent variables

The independent variables consist of four components: news media consumption patterns, news media content and news media format. Each of these components will be briefly discussed in the remainder of this paper.

3.0 Research Methodology

Research Design

The research design of the study is shown in Fig. 2.

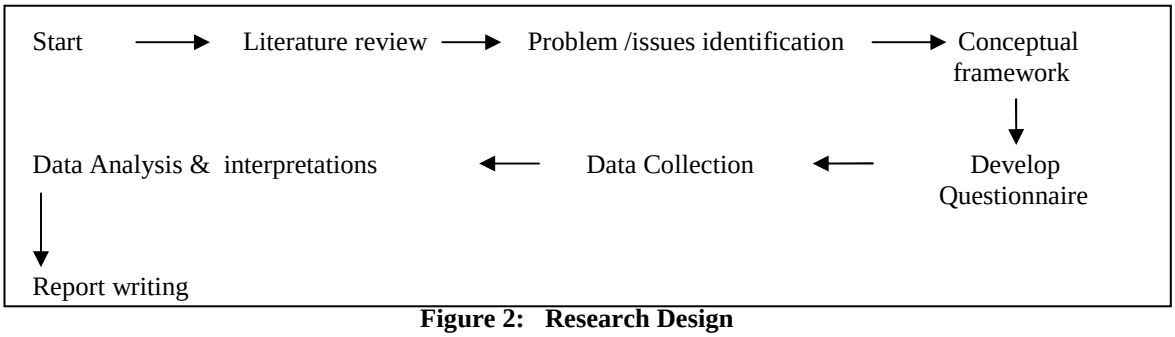

Figure 2: Research Design

Self-Administered. Questionnaire

The study adopted survey research method and instrument used was self-administered. questionnaire and the development is in Fig 3.

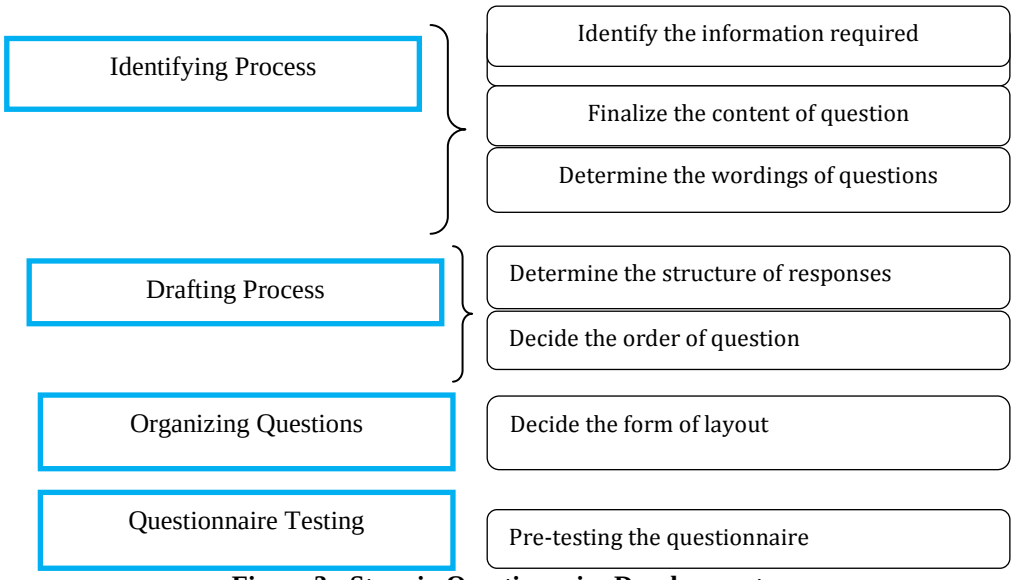

Figure 3: Steps in Questionnaire Development

Population and Sample Size

According to the sampling size guideline table by Krejcie and Morgan (1970), the 2500 young adults in the Selangor Public Library population is close to 2600, therefore the sample size suggested is 335. Thus 100 questionnaire were distributed to the each groups:

Age	No. of questionnaire	Types of respondents
15-17	100	Secondary school leaver
18-21	100	Pre-University/A-Level students
22-25	100	Diploma/Degree/Post Graduate
26-29	100	Part-time/Full time worker

The variables used the Likert Point scaling with five anchoring being 1 for Strongly Disagree and 5 for Strongly Agree. The questionnaire was segmented into six parts with Part 1 capturing demographic information. Part 2 capturing news media consumption patterns , Part 3 capturing news media content, Part 4 capturing news media format /sources, Part 5 on value of news and Part 6 the open ended questions.

Data analysis and discussions

Part 1 Demographic profiles of respondents

This section summarizes the demographic profiles of the respondents by gender, age and academic status. All these variables have been analyzed and interpreted separately as described below.

Table 2: Demographic profiles of respondents

		Frequency	Percent %
Gender	Male	169	50.4
	Female	166	49.6
Age	15-19	67	20.0
	20-24	135	40.3
	25-29	133	39.7
Academic status	Secondary school leaver	67	20.0
	Pre-University/A-Level students	67	20.0
	Diploma/Degree/Post Graduate	133	39.7
	Part-time/Full time worker	68	20.3

Part 2 News Media Consumption Patterns

Table 3: News Media Consumption Patterns

		Responses	
		N	Percent
Types of news media preferred	Search engines	234	26.9
	Printed newspaper	167	19.2
	Social media	167	19.2
	Television/radio	167	19.2
	Online newspaper	135	15.5
Factors influences reading	Being well-informed	335	34.5
	Satisfy own curiosity	235	24.2
	To enhance knowledge	201	20.7
	Daily routine	201	20.7
Devices use to access news	Smart phone	235	29.1
	Television/radio	235	29.1
	Desktop/laptop	169	20.9
	Printed newspaper	168	20.8
Reading materials Sources	Library/friends /family	335	40.0
	Internet	335	40.0
	Bookstore	167	20.0
Most Preferred News	National	166	49.6
	Entertainment	101	30.1
	Sports	68	20.3

Majority of respondents (26.9%) prefer search engines such as Google and Yahoo to attain updated news. This represents merely quarter of respondents have been practicing to obtain news and information via online. Meanwhile, the term 'Go Google' has been used widely to emphasize information searches online. The findings are supported by Ito (2008) and Qayyum et al.,(2010) This largest internet browser yet a powerful search engines in the world has won in terms of sophisticated search results. It able to hosts millions of data and information which accessible from any part around the world and created a phenomenal nowadays. Besides Google, Yahoo also a feature which provides latest ranking news based on worldwide searches. Meanwhile, highest rank factor that influences the respondents to read or consume news is to be being well informed (34.5%) and equipped themselves

with up-to-the-minute information. The smart phones and television/radio are the favored device to access news. 40.2% of the respondents agree to retrieve reading materials from library/friend/family and internet sources. The most preferred news among the young adults in Selangor are the national issue followed by entertainment and least preferable is sports.

Part 3 News Media Contents

The respondents agree to frequently browse the internet for news reads during free time. This has matching the earlier statement of devices use to consume news. They read thoroughly or discuss with friends and family (60.3%) on particular news. Merely half of respondents (59.7%) ensure that they will always get access to e-sources materials such as online news, social media and television/radio rather than printed materials. This represents the needs of news is very important which also refer as news anxiety. The syndrome explains as craving towards news and information which will cause the feeling of being left out from friends/colleagues/family. The highest mean score is to read online news as they are accessible, portable, environment friendly and convenient. (4.3015) which is supported by Kaufhold (2010) and Penenberg (2004).

Table 4: News Media Contents

Statements of News media content	Mean
I prefer to read online news as they are accessible, portable, environment friendly and convenient.	4.3015
I prefer to make a discussion with friends and family about particular news	4.2
The transformation of printed newspaper to online news give a good impact towards my news seeking and retrieval.	4.0955
I am satisfied with online news services and application nowadays.	3.6985
I always get access to e-sources materials such as online news, social media and television/radio rather than printed materials.	3.597
I frequently browse the internet for news reads during free time.	3.3672
I subscribe to news alert applications via emails and SMS.	2.203
Total	**3.6375**

Part 4 News media format/sources

Studies shows that 67% of respondents agree online news is a trend in news consuming and also 40% practice will flip through printed newspapers if only no other choice. Other ways to get news resources are from family, friends, colleagues. Additionally, the format of news sources that most preferred represented by 49.6% is via online as they provide other features such as audio news, eye-catching graphics, interesting typography and entertaining advertisements. Online news able to provide these features and feed the young adults with visual information simultaneously. Apparently, the researcher also highlights over the issue of environmental friendly sources. There is also great concern show from 30.4% respondents agree printed newspaper consumes paper wasting and mess. The findings of this study are not similar to Chyi & Chang (2009) and De Waal, Schoenbach, & Lauf (2005).Table below shows the highest mean score received from the statement of online news is a trend in news consuming.

Table 5 News media format/sources

Statements of News media format/sources	Mean
Online news is a trend in news consuming.	3.8
I will flip through printed newspapers if I have no other choice.	3.797

Printed newspaper consume paper wasting and mess.	3.7075
I prefer to opt online news as they provide other features such as audio news, eye-catching graphics, interesting typography and entertaining advertisements.	3.597
I prefer to seek news through internet browsing.	3.4985
Other ways to get news resources are from family, friends, colleagues.	3.397
Total	**3.6328**

Recommendations

General

Many studies conducted in modern country agreed the best highlight to understand young adults information behavior is learning by experience and practice. Most researchers work on focusing their needs and how far the young adults response towards their information need. In this particular study, young adults in Selangor retrieve news needs from digital format and less preferred printed news media.

Authorized parties, government, non government agencies, school and parents play crucial role in order to ensure news accessible via online are filtered, as negative news content easily contagious plus misinterpreted. As been practiced in many Asia and Middle East countries due to internet censorship are such as Turkmenistan, Vietnam, Tunisia, Syria, Iran, Saudi Arabia, Republic of China, Cuba, Burma and Iran. Meanwhile, top of the list is North Korea where only 4% of total population able to access to internet. Basically young adults news consumption in their daily lives are mostly extent to several area namely entertainment, sports, leisure readings, education and edutainment. Thus, news are being shape according to one's background and interest. Young adults in Malaysia should be educate from early age to read, segregate, appreciate information in order to create later knowledgeable generation.

Building Libraries for a Better Tomorrow

Majority of Malaysian found library as sacred place, passive, plain and not interested in any of activities organized as compared to other side of advanced countries, young adults been nurtured to visit library often and utilized any services provided. Most local young adults would only turn to libraries as second option to consume news and information. At this point, young generations of librarian and information specialist are well trained to help young adults information avoidance towards libraries. The brand new librarians or information specialists are more aggressive, approachable, IT savvy and creative.

In light of the rise of social media and internet, information seeking via online has taken over the libraries as main source of knowledge. Accordingly, the outright planning for libraries out there to face this challenge is to build collection and services to suit for people in the community. People tend to pay attention to something new, vibrant and spacious place which totally provide fresh environment and feels. Additionally, technologies are in and out of favor quickly. In this case, libraries should apply advertising as number one rule which is to participate generously in community activities so that people around will remember their presence and build its branding simultaneously.

Malaysia should address major consideration of building future libraries based on users information behavior in order to build great collection as well as services. According to YALSA Research Agenda 2012–2016, the best way to build a library is to have better understanding of users behavior in a way of how they seek, manage and use information. This strategy has been used in advance

countries to build libraries purposefully based on sociological, living routine and information practice of the community.

Young Adults' Information Practices

From Dervin (1983), Ellis (1989), Kuhltau (1989) to Wilson have proposed regarding information behavior models across areas and found common results which user will engage with information seeking process when there is emerging interest or needs. Since that, recent researchers have been working to study information behavior to suit according latest lifestyle which requires less seeking process especially in internet era. As to date, there are few researchers been using the earlier information seeking process to develop latest model of everyday life information seeking as practice socially and culturally by young adults. Recent models apply digital information from various sources involve during this process such as television, newspapers, radio and Internet. For that reason, many researchers suggested young adults are increasingly mixing online and offline sources, which integrating technologies into their everyday information practice.

Future Research

As many studies found were mainly focusing on adults or children, there are limited considerations on young adults Information Behavior (IB) happening in today's world. Other researchers may pay attention more towards either on elderly generation or kids to suit themselves with advance technology. Nonetheless, researchers would work and concentrate on different perception on young adults information behavior. The term young adults itself is defined in many category which also affected by country, religion and background.

For future research, this study would perhaps to be covered in other location as well. This study was conducted in urban area where internet and devices are available easily. Meanwhile in other location or community, the survey could reveal the exact behavior among young adults towards news consumption in their daily lives. Moreover, the framework of this study could be used as platform to conduct future studies and provide value-added results.

This study was conducted in public library using quantitative research method to measure the fundamental situation of Malaysian young adults. The method used could be enhanced by using qualitative research methods such as focus group, interviews in order to gather better view and unlimited response. Thus, may provide other new discovery while involving verbal communication. Additionally, quantitative method is very structured whilst quantitative will provide wide possibility of results but may need longer time.

Future researcher could also take into consideration of young adults preferences of libraries role as their ultimate option to seek information and knowledge. Some may not interested to visit the library as the usual and traditional building are plain, quiet as well as bored.

Conclusion

Apparently, young adults news consumption in Malaysia has change literally from printed towards digital platform. Schools and parents have started with subscription into e-news which can be accessed anywhere and at anytime. Besides, news are easily available via online and provide more updated, reliable and less time consuming. Kids and young adults nowadays can be seen using gadgets and smart phones in their daily lives to access internet, games and social networking. However, there are partial of young adults prefer printed newspaper as there limited access and devices in remote area. All the research objectives were successfully achieved at this stage of this study.

Abstract

One of the key objects for modern society is the social and economic well-being of the population. State tax policy is a powerful regulatory tool for social and economic development. In this sense, it is not just fiscal but also a variety of other regulatory objectives - economic, social, environmental, international. In this article we analyze state tax policy on example of consolidated groups of taxpayers. We classify requirements and conditions for the consolidated groups of taxpayers used in developed countries with special focus to the Russian model. We examine the strengths and weaknesses of existing models of big business taxation. Special World practice shows that in economic globalization, transnational corporations are a vital tool in competition of developed countries for international markets and leadership in the world division of labor.

Keywords: tax, consolidated group of taxpayers, taxation, tax revenue, regions, profits tax.

Introduction

The origins and implementation of consolidated taxpayer system in developed countries cover the period from the beginning of the 20th century to the present. In particular, consolidated tax regime was introduced into tax legislation in Austria – in 1902, 1972; in the UK – in 1967; in Denmark – in 1936, 1960; in Spain – in 1942; in Italy – in 2004; in Luxembourg – in 1981; in the Netherlands – in 1940, 1969; in Portugal – in 1987; in Finland – in 1987; in France – in 1971; in Sweden – in 1965; in the United States – in 1917. By 2014 year trend of the introduction of consolidated taxpayers spread virtually worldwide (table 1).

In Russia institute of the consolidated group of taxpayers (CGT) exist from January 1, 2012 according to Federal law of Russia dated 16.11.2011 № 321 «On amending parts of the first and second tax code of the Russian Federation in connection with the establishment of the consolidated group of taxpayers». However, already in the year 2014 was imposed a moratorium on creating new groups until 2016, and then until 2018.

The criteria for creation of consolidated group of taxpayers

We consider in more detail the criteria for creation of the CGT for Russia, USA, France, UK, Japan (table 3). France, Japan, UK and USA are major countries using the consolidated taxation since the beginning of the 20 century. Their experience could be sufficient to correct Russian model.
We compare requirements to companies according to:

1. Actors-participants in CGT.
2. Basis of association (obligatory or voluntary).
3. Equity participation in the capital of subsidiary companies.
4. Requirements to the total cost of assets in a group.
5. Requirements to the amount of the total revenue for the calendar year preceding the year in which companies are submitted to the tax authority the registration documents for the Treaty on the establishment of CGT.
6. Requirements to the total amount of value added tax, excise tax, corporate profit tax and mineral extraction tax paid during the calendar year preceding the year in which companies are submitted to the tax authority the registration documents for the Treaty on the establishment of CGT.
7. Characteristics of a group.

Table 2: Requirements to companies in CGT

1. Which companies may create CGT:	
Russia	Only Russian companies
USA	Can be virtually all companies registered in this State, except in the case of certain types of companies. For example, companies that is exempt from tax
France	Resident companies of France
UK	The principle of «Group tax credit» (analogous to a CGT). Get under this principle have the right to virtually all companies, regardless of whether they are resident in the UK or not. However, there are exceptions, such as gas and oil industry companies are unable to obtain this benefit to income derived from oil and gas extraction, and a life insurance company can apply group tax relief only to income taxed at the main shareholder
Japan	All kinds of Japanese corporations, as well as cooperatives, representing blue tax return (Japanese income tax returns are subdivided into two types: white and blue. All taxpayers may apply to the territorial tax office for permission to represent the blue tax return. To obtain the right to use this declaration a taxpayer must agree on the use of certain special accounting rules. In doing so, the taxpayer gets a number of advantages: the possibility of applying accelerated depreciation rules, shifting losses recognized for tax purposes in future periods). Cooperatives can enter the CGT only as head of the organization, but not as a dependent.
2. Obligatory or voluntary basis of association	
Russia	Consolidation is the right, but not an obligation. The degree of consolidation: a) when creating the CGT on the basis of a decision of the head of the organization of the group should be composed of all the subdivisions of the head organization; b) when creating the CGT on the basis of the contract on the occurrence of all of the subsidiaries in the group is not required.
USA	Voluntary basis of association.
France	
UK	
Japan	Decision on the establishment of the CGT cannot be cancelled. The group is required to enter all companies, totally dependent on the head.
3. Equity participation in the capital of subsidiary companies	

Russia	Not less than 90%
USA	80% (participation in the general meeting of shareholders and cost)
France	Not less than 95%
UK	75%
Japan	100 %
4. Total cost of assets in a group	
Russia	Not less than 300 billion rub
USA	No limits
France	
UK	
Japan	
5. Total revenue of a group	
Russia	Not less than 100 billion rub
USA	No limits
France	
UK	
Japan	
6. Total amount of paid taxes by a group	
Russia	Not less than 10 billion rub
USA	No limits
France	
UK	
Japan	
7. Characteristics of a group	
Russia	Possible unification of gains and losses of the entire group and the fulfillment of tax obligations on behalf of the group of the parent organization.
USA	No data
France	Possible association of gains and losses of the entire group and the fulfillment of tax obligations on behalf of the group of the parent organization.
UK	The costs taken into account in the taxation (reduce profits) can be moved into the group up and down vertically as well as horizontally. The operation to move assets between members of the group are not taxed.
Japan	Each participant first CGT computes its own taxable income and adjustments based on the current law on profit tax corporations. Then headache organization unites taxable income of all participants and performs adjustments on the basis of the consolidated group is already based on the rules of consolidated taxation.

We can see that advisability of setting any quantitative indicators of CGT activities is doubtful.

Equity participation in the capital of subsidiary companies in consolidated group of taxpayers

Analyze the international practice of requirements to the companies to become members of the consolidated group of taxpayers shows, that in every country there are restrictions of equity participation in the capital of subsidiary companies. The limits of this criterion for countries range from 50% (Germany) to 100% (Australia, Denmark, New Zealand, Japan), taking into account both direct and indirect ownership. The criteria for the minimum equity capital for companies seeking to use the group mode of taxation in different countries are represented in the table 3.

Table 3: Criteria for equity participation in the capital of subsidiary companies

Country	Minimum equity threshold for associated enterprises, %
Australia	100
Austria	75
United Kingdom	75
Germany	50
Denmark	100
India	100
Spain	70–75
Italy	50,1
Luxembourg	95
Mexico	50
Netherlands	95
New Zealand	100
Norway	90
Portugal	90
Russia	90
Singapore	75
United States	80
Finland	90
France	95
Sweden	90
Japan	100

In Russia this principle is discriminatory and contrary to article 3, paragraph 1 of the Tax Code, which provides for the universality and equality of taxation. The establishment of the right of use depending on the consolidation of absolute indicators for financial and economic activity (value of tax liabilities, revenues, total assets) are actually supported by preferential taxation of major companies. Studies by Russian scientists, according to the results of the year 2014 is actually created on 16 CGT, which included more than 398 organizations (mostly large companies, oil gas, oil refining, iron and steel industry and the communications industry). However, most countries, including Russia, create a special simplified tax regime seek to support small and medium-sized businesses. In addition, this approach leads to a violation of market competition: the dominant industry group of companies will have an even greater advantage because competing companies, which do not meet the criteria, will not be able to use this mechanism.

To reduce the discriminatory impact we suggest reducing participation in capital of the subsidiaries of the group in Russia from 90% to 84%. This value is the average value among countries applying consolidated group of taxpayers (fig. 1). The change in share would allow a broader range of companies qualify for merging with other companies not only in companies in the gas, oil, petrochemical, metallurgical industries, etc

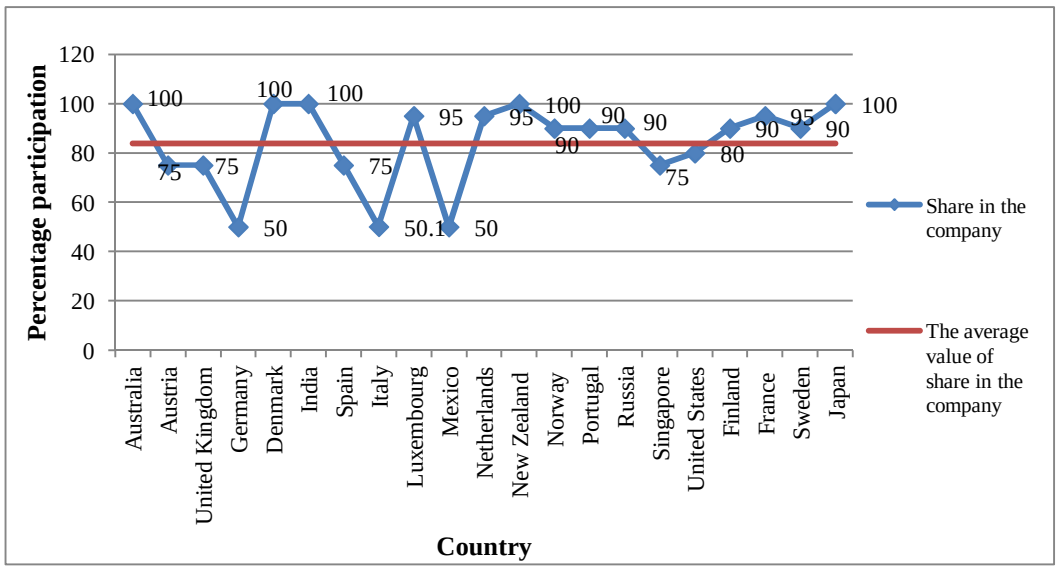

Figure 1: Percentage participation in consolidated group of taxpayers

Conclusion

State tax policy is a powerful regulatory tool for social and economic development. In this sense, it is not just fiscal but also a variety of other regulatory objectives are economic, social, environmental, and international. Implementation of state fiscal policy, taking into account all the interrelated fields of public and economic life cannot be carried out offline. These activities should be based on the basic principles that take into account the current economic situation, both in the state and in the world. Fiscal policy should take into account numerous factors of an economic, social, legal, organizational order affecting the normative functioning and development of tax relations for large organizations.

We propose to reduce the share equity participation in the capital of subsidiary companies in consolidated group of taxpayers in Russia from 90% to 84%. The change in share would allow a broader range of companies create CGT. The main reason the legislator limits the range of potential users of this system of taxation is «fear» of uncontrolled abuse of consolidation and striving to determine in advance the list of companies that will be able to take advantage of its benefits. To avoid potential abuse of consolidation, in our view, it is appropriate to ensure proper monitoring of the activities of the group on the basis of the creation of the methodical providing of tax administration, accounting and auditing of CGT.

Abstract

The research aims to reflect the changes the paradigms in the context of internet technology development. There were taken into consideration realities and current economic conditions, development of the Internet as a global technical architecture and interaction between producers, industry and consumers, all contributing to a new form of collaboration, distribution, promotion and global business. The present research emphasizes the issues brought by innovation to a particular industry and the switch of paradigm in terms of business trend when assessing producers, consumers and the industry itself. The internet offers a wide variety of platforms, applications, websites, online discussion forums, specifically built for each dimension of the industry, delivering products and services to those interested to use them either for business or private purposes. Within the context of the present paper, the transfer of technology refers particularly to change between two generation of technology, not to transfer of intellectual property

Keywords: downloading, internet of things, transfer of technology, streaming

Introduction

Business dictionary states that transfer of technology represents the movement of innovations, knowledge, and techniques from one organization or country to another through assistance, investment, licensing, trade, or training. However, within the context of the present paper, transfer of technology is analyzed only in terms of transition from one generation of technology to another generation (an improved version or a newer one).

Taking into consideration the development of internet technology and the informational society across the planet, there is a confirmed trend to implement several activities in cyberspace, common and accessible by anyone, anywhere, anytime. From socialization and communication among people up to doing online business and everyday activities due to the easy access to information, the Internet has become a vital factor for personal and professional development. This has resulted in a wide variety of applications and platforms, specifically designed according to each industry and activity. Cyberspace has managed to capture much of the public interest by providing everyone the opportunity to be able to promote and manage activities in the digital environment. Unlike classical promotion, the Internet is still an experimental environment where there are no clear rules of operation, but has a strong development trend of substitution and the future of classical promotion. The totality of efforts to promote a brand, a product, service, artistic or cultural value creation, customer relationship management, delivering messages to consumers has become easy and almost instant

According to technopedia.com, the Internet of Things (IoT) is a computing concept that describes a future where everyday physical objects will be connected to the Internet and be able to identify themselves to other devices. The IoT is significant because an object that can represent itself digitally becomes something greater than the object by itself. No longer does the object relate just to you, but is now connected to surrounding objects and database data. When many objects act in unison, they are known as having "ambient intelligence."

Given this, all types of industry should switch the main activity in order to include the new technologies. The present study took under analysis the entertainment industry as the online environment allows rapid and complete presentation of services and products for the selected industry as well as an effective, quickly and directly interaction with consumers, promoting ongoing communication, analytical systems, explanations and comments, results measurement and boosting productivity growth for actors in this field.

Key concepts regarding entertainment industry within "internet of things"

Downloading music from online music retailers like iTunes, Amazon or Google Play means that the files are transferred and stored directly to the own device. Once the files are stored, there is no need for an internet connection. A fee will be paid per song or per album and it is then free for someone to transfer to other devices as desired.

Streaming music is a different approach, because the music is not owned. It is consumed via the internet, Wi-Fi or mobile data networks. Most online streaming services offer a free option with advertisement support and/or metered listening, while pushing the client towards a premium tier that offers ad-free, unlimited access to libraries of over 20 million songs and the ability to download music for offline listening.

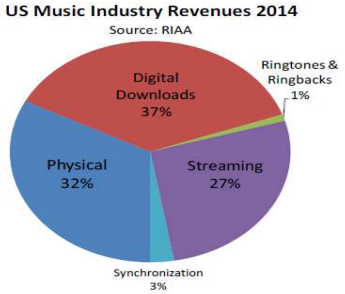
"Streaming" is a common word that is largely used when referring to shared media (audio/video). It describes the act of playing digital online media on one device while the media is saved on another, for example, a portable device. The digital media could be stored on a computer, media server or network attached storage device (NAS) on your home network, an iPod, Tablet or a Smart Phone.

A network media player can access a particular file and play/stream it on your home audio equipment. That particular file doesn't have to be moved or copied to the specific device that is playing/streaming it. Music sites like Pandora, Rhapsody and last.fm, are websites that stream video (i.e. movies, video clips) and audio (i.e. Music) to your portable device, computer and/or network media player/streamer.

Situation awareness

The international company Apple took over Beats Electronics investing over 3 billion USD, fact revealed by statistics that show that Apple's revenues out of the audio streaming services surpassed the digital downloads sales, according to Warner Music Group official.

In 2014, the United States Music Industry was registering a revenue increase by 2%, up to 4.86 billon USD in the first quarter and in the second quarter, small decreases by -0.5%, achieving a total of 6.97 billion USD. The ratio between revenues was of 37% from the digital sales, 32% from physical media, 27% from streaming and 2% from phone ring-tones.



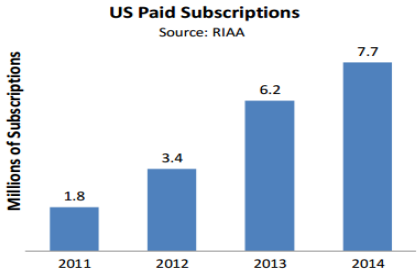


Fig.1 USA music revenues in 2014 **Fig.2 Payed subscriptions in USA in 2014**

Ten years ago, the CD was still the dominating media of the music market, but the new services that permitted the acquisition and the downloading of digital music were in full advance. Apple stepped into this market in 2003, proving for the first time that there are great chances to make profit out of online digital music sales. iTunes Music Store became in a short period of time the largest trader of digital music sales in the United States in 2008 and the largest in the world by 2010. Other similar platforms have appeared shortly after, having the same purpose on the market (Amazon MP3, Beatport, Junodownloads etc.).

The way the analog storage on compact cassettes or vinyl was replaced by the CD, and this on his turn was overtaken by the MP3 digital format, it is plausible that for the selling of digital music, even the online services must confront with the new platforms created by the market evolution, younger and more dynamic: streaming Services like Spotify, GooglePlay Music, Deezer or Pandora.

In the first quarter of 2015, the revenues from the Warner Music Group's online streaming song catalogue, have noticed an increase by 33%, while the digital physical format sales only by 7%. Warner Music Group is the largest company from the group of "the three big ones" (Warner Music Group, Universal and Sony) that announces this change, a sign of the redefinition of the way the public wants to consume music.

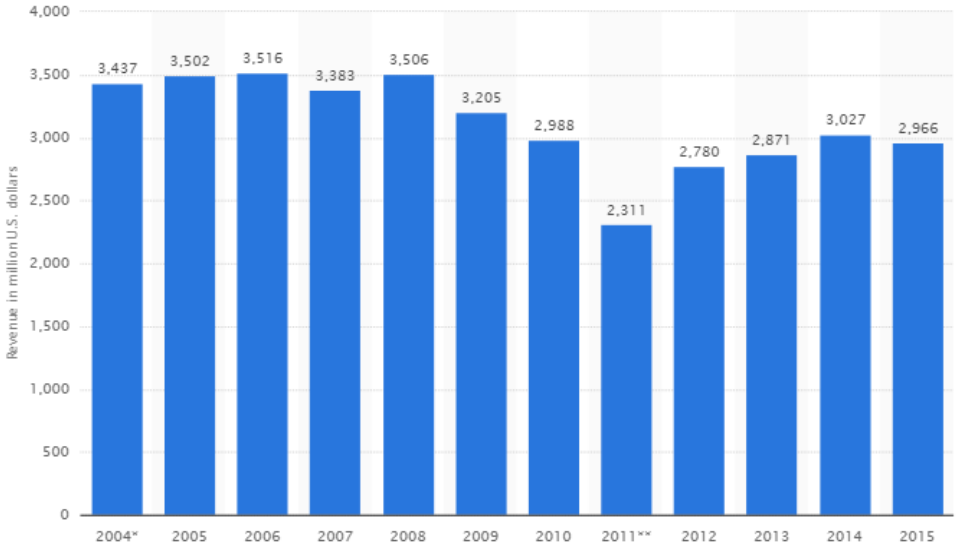

Figure 3: Warner Music Group revenues between 2004 and 2015 (in millions USD) (source: www.statista.com)

At the moment there are no straight conclusions to the question on how the commercialization model of the streaming services will look like. Spotify became famous because it offers free access and it is sustained by advertisement and special subscription business models, but model is heavily critics from the artists, due to the fact that it generates low income.

Streaming VS. Downloading

The idea of “owning” music in the digital age is a bizarre one, due to the fact that the digital music is not a physical product. When the audience wants to listen to music, you press the play button and the melody comes on regardless of whether it is downloaded or streamed, as states Chris Smith (2015).

Within the paper’s context, the next generation of technology is represented by streaming. The digital content users are listening to streaming video and music as it comes to their computer, portable devices or network media players. A website or portal that streams video or audio will often have a "buffer" embedded in the transmission. Several seconds of video or audio content is streamed to the computer or network media player in order to keep the digital stream playing and to avoid interruptions in case of internet lags or disconnections, as said Gonzales within “The Difference Between Streaming and Downloading Media”

A fast internet connection is required for a flawless transmission and for no pauses or “hiccups” in the audio/video playback. Higher quality video / high definition video with digital surround sound requires a faster connection. Audio Video ("AV") routers or Gigabit routers are needed to be able to stream high definition digital content to more than one device or player.

As a standard, video streaming websites are able to determine the quality of the video streamed to your device, based on the algorithms that are able to estimate internet speeds. A streamed file can be played from many sources. The source of the streaming media must be connected and turned on at all times, or the streaming does not function. When streaming from the internet, it is not only the speed of the connection that guarantees a stable. Different factors such as the amount of traffic on the streaming website – in other words, the number of users watching videos or listening to music at the same time - and the speed of the website's server connection can influence the quality of the streamed signal received by the users.

Streaming files are never saved on local devices. Streaming media is either free, or you are charged a monthly subscription to access the media, such as with Spotify, Netflix, iTunes, Digitally Imported and Rhapsody. A user can only play music on a subscription website if paying. Once there are no more payments, the digital media is no longer available.

In which the old generation (downloading) is concerned, a portable device connects to the source of the digital files, then copies and saves them to the local hard drive. There is the need to wait until the download is complete before the digital audio/video content can be used. Services like iTunes and Vudu, allow the user to watch while a movie downloads after a sufficient amount of time. The user is allowed to copy the files or move them to other hard drives unless the files are copyright-protected, as stated by Barb Gonzales (2015).

The downloaded files can be streamed to other devices once it has been saved on a local hard drive. Downloaded files are available whenever a user wants to play them. All network media players are able to stream files from a user’s home network. Some media players are equipped with hard drives or can dock a portable hard drive to save files. Understanding the difference between streaming and downloading media, can be useful for choosing the right media player for a user.

Conclusions

Downloading allows the user to own the music and listen without worrying about whether he/she can connect to the internet or whether they use too much data. It also gives artists a larger slice of the pie, being remunerated accordingly, as stated by Barb Gonzales (2015). On the other hand, streaming services allow the user to listen to more music at a lower cost, often for free, as well discover interesting new music without making any more investments. It also ends the need to store music files on portable or home devices.

Some artists are still holding out because of the lower streaming revenue. This means the user will have to buy the albums from download services or import from own CDs, fact that is nowadays legal, in order to listen to them digitally. If the users prefer rarities, like live concerts, acoustic sessions, bootlegs, B-Sides, rare remixes etc. from their favorite artists then thy may have to download these as well.

Furthermore, Cloud Computing is the next generation of music, film and photo sharing distribution /purchasing system that allows the internet users to access big data instantly from all parts of the planet, from home, office or mobile technology devices.

Multidimensional Reliability Concept in Dynamic Control Structures for Executing Production Projects

Iwona Lapunka, Opole University of Technology, Department of Project Management, Opole, Poland, i.lapunka@po.opole.pl

Abstract

Distinguishing routine processes and tasks from one-time orders/projects in a production system is fundamental in contemporary enterprises offering custom-made products and services. These types of production systems, identified with discrete manufacturing, are characterized by an increasing complexity of decision problems in their control structure and a significant vulnerability to disruption. The likelihood of disruption depends on the reliability of the production system, the impact of the environment, and on unforeseen random factors. In this paper we postulate employing reliability theory to control systems for production processes during the execution of project driven orders, with the long-term goal of elaborating a multidimensional reliability concept in a dynamic control structure for the execution of production projects.

Keywords: reliability, production system, project driven order, disruption, controlling project execution, project dashboard.

Introduction

In the contemporary highly competitive free market economy, shaped by the laws of supply and demand, production enterprises must constantly strive to employ improved production management methods. The driving force is the pressure to reduce production costs while increasing the efficiency of the production system. The three basic aspects of business activity: quality, cost, and supply require continual improvements. This relates to the project approach to production orders, which are executed in accordance with the "iron triangle" of project aims (time-cost-quality). Transitioning from the traditional approach used for preparing variants, planning and managing orders towards the project approach is of particular significance in the case of flexible production (piece or order-based production, short production series, large product turnover, changing requirements of customers, minimizing the time between conceiving a product and its manufacture). Proper organization and, subsequently, controlling production flow is paramount for delivering a product of requisite quality in a timely fashion. At the same time, the complexity of planning issues and their links with the rest of the production preparation system is on the rise.

Unique, one-time production processes constitute the majority of orders received by enterprises; they require detailed analysis, organization, and selecting appropriate management methods. Therefore, they are often treated as production processes according to the classical PMI definition formulated in the PMBOK Guide (PMI, 2013). According to Wysocki (2013), a project signifies a sequence of unique, complex and interrelated tasks differing in nature, but having a common goal and set for completion in a specified time frame, within an assumed budget and according to adopted requirements. The aim of each project execution is to attain expected results (parameters), while striving to satisfy the needs of the customer.

Nowadays the meaning of thus understood forms of production process execution in dynamic organizations and the requirement to employ specific management methods are embodied by the concept of "management by projects". The current requirements of effective project management are:

(1) high level of communication, (2) flexibility and short response time, (3) prompt decision-making, (4) solving unstructured problems, (5) effective planning and controlling under the conditions of uncertainty, (6) determining major stages of project execution (milestones). For production enterprises this often signifies the need to elaborate a completely new approach, adopting methods typical for project management in organizations with a predominance of operational and repetitive actions. Discrete manufacturing, understood as the production of distinctive, custom-made product units, in compliance with precise specification of requirements, is increasingly identified with the term "project driven order" (Pisz, Łapuńka, 2012). Implementing changes in the way business is conducted, and distinguishing between routine and unique tasks (projects) in a production system has become indispensable.

The paper signals the need to elaborate a multidimensional reliability concept in the dynamic control structure for the execution of production projects, highlighting the need to carry out more advanced follow-up studies. Employing reliability theory to the control system for production processes during the execution of project driven orders requires considering a multidimensional context, encompassing, among others: (1) maintaining the system executing operational tasks at the required reliability level; (2) maintaining an appropriate level of accessibility of equipment, staff and materials; (3) maintaining necessary resources and supporting the operational requirements of the system. A synthetic presentation of individual solutions, together with a multilevel decision-making structure is the basis for elaborating a consistent reliability concept in the control system for the execution of production projects. The proposed concept may find practical application in controlling the dynamic structure of multi-product production.

Dynamic control structures for the execution of production projects

The analyses carried out as part of this study are concerned with planning limited to single-piece or low-volume production, mostly on order taking into account customers' changing requirements as well as the complexity and substantial duration of production process execution. The term "production project" or "project driven order" assumed in the paper is understood as a unique (one-off) complex production process concluded in a finite time frame, with distinguished start and end points, executed collectively (by multiple units), performed relatively independently from the routine business of an enterprise (yet remaining within a specified production system), and using dedicated methods and techniques. According to another definition (Wróblewski, 1993) a production process is an organized set of actions for coordinating the flows of materials, information and energy during the execution of a technological process. With regard to their course and continuity industrial manufacturing processes can be classified either as discrete or continuous.

Currently, discrete processes, i.e., flexible, temporally and spatially coherent complexes of operations, with a structure adapting to the quality-quantity characteristics of manufactured goods (Durlik, 1995), are treated as manufacturing technologies, dominated by non-continuous flows of energy and materials, whose variables of state are multi-valued functions of time. It is estimated that ca. 80% of products are manufactured through discrete processes.

The order of decisions concerning what, where, when and how much should be produced has a significant influence on the operation of a production control system. If the first step is to decide where, i.e., in which organizational units production is to take place, and only then the decisions about what, how, when and how much each unit should produce are made, production control is typically capacity-oriented. Such an approach is typical for repetitive, mass and high-volume production. In contrast, if the first step is concerned with what, how, when and how much should be produced, and only then are production units assigned to production orders, production control is material-oriented (Sitek, 2000). Material-oriented production control is typical of medium-series, short-run and single-piece production (cf. Table 1).

Discrete production systems are characterized by a large number of variables describing system state, such as information about equipment, manufactured products, materials, operations etc. Therefore, decision problems that occur in discrete production control systems may be highly complex, both in

terms of size and the density of their mutual connections. Managing project driven orders, especially in the context of a multi-project environment tends to expose the multilevel and multilayered structure of these issues. The nature of the decisions to be made varies with the level:

- at the top level, decisions are global: economic, strategic, investment, assortment; based on market, price and resource prognoses;
- at a lower level decisions concern businesslike planning, scheduling and controlling production (including project driven orders);
- the lowest level is concerned with process control, equipment and machinery.

Table 1: Project driven orders in production control system

	Material-oriented production control		Capacity-oriented production control		
Production type	single-piece	low-volume	series	mass	continuous
Production size	single units	small	medium	very large	continuous stream
Product variability	each product is unique	significant	rare	small	non-existent
Frequency of changes	continuous	frequent	occasional	non-existent	non-existent
Individual equipment	universal	universal	somewhat specialized	specialized	specialized
No. of operators	large	large	smaller	small	small
Level of qualifications	high	high	medium	low	low
Cost of capital	low	low	medium	high	very high
Unit costs	high	high	medium	low	low
	Project driven order				

Source: own elaboration based on (Wróblewski, 1993)

Proper project execution control is determined, among others, by: (1) assigning means for project control, (2) cooperating with contractors and subcontractors, (3) monitoring the project and reporting on its status, (4) schedule risk analysis (SRA), (5) earned value method (EVM) analysis, (6) the principles for modifying plans during their execution.

The execution of production orders according to the project approach renders the following benefits: (1) reducing the time of executing actions, (2) reducing costs, (3) reducing material and human resources necessary for project execution, (4) finishing the entire undertaking and its individual stages in a timely manner, (5) continuous supervision of order execution, (6) reducing uncertainty related to the execution of subsequent stages, (7) reducing unit costs (both fixed and variable) (Kasperek, 2011).

Practical implications of reliability theory for complex systems

The reliability of a technical object in the standard sense is a property determined by the probability of meeting requirements. Often understood as the probability of success, i.e., the object meeting a given requirement, or as the probability that in the time interval (0, *t*), the changes of certain properties of the object will remain within a range specified for the object (Kiliński, 1971). Therefore, the measure of reliability is the probability of fault-free functioning of a given object under the assumed operational conditions and over a given useful lifetime. Reliability can be determined for technical objects of various complexity levels: parts, subunits, units, mechanisms, assemblies, entire devices or systems. At each of these levels the same reliability characteristics can be applied, interrelated in a specific manner (sequential, parallel, sequential-parallel and parallel-sequential structures) (Migdalski, 1992; Słowiński, 2002).

To determine the reliability of technical objects, research methods are applied, which allow to obtain and process information about those properties of technical objects that become apparent during use and that demonstrate their usefulness in the execution of tasks, for which they were designed and manufactured. Mathematical models, and probabilistic models in particular, are widely applied in reliability theory. The most common models used to describe the reliability of equipment and devices are the mathematical models of simple technical objects, classified as: (1) non-renewable objects, (2) complex objects, (3) renewable objects, and (4) complex renewable objects.

Furthermore, as a result of reliability analysis of the human-technical object system it was assumed that human reliability is defined as a capability of meeting requirements with minimal probability of error under given conditions and time frame. This property is often associated with resistance to disruptions that occur in the course of work (Ignac-Nowicka, Gembalska-Kwiecień, 2014). Among many classifications of human errors proposed to date, the division into systematic and random errors appears to be the most appropriate. The probabilistic approach (setting out to describe the probability of an error occurring) is typical for the studies of human reliability in relation to risk analysis, where human error is treated on the same footing as a technical fault or malfunction in the operation of a machine. The number of human and machine errors serves as the basis for calculating the coefficient of reliability for the entire system. As for the so-called operator errors, a number of types of action errors can be distinguished; owing to their significance in the project approach, these will be analyzed in detail in follow-up studies (Rouse, Rouse, 1983):

- lack of appropriate response to a signal,
- late response,
- response in time, but incomplete or inappropriate,
- unnecessary response due to chaotic activity,
- premature response,
- unprompted response in the absence of an external signal, premature execution of a procedure,
- Response opposite to the desired response or inaccurate.

Gathering data on human error is fundamental for elaborating measures of human reliability. The long-term goal is the prediction of the reliability of systems, where a human plays a specific role. In the elaborate list of possible mechanisms of human error the decision-making mechanism deserves particular attention. According to Swets, Tanner and Birdsall (1961), the authors of signal detection theory, the behavior of a human operator admits a mathematical description. Within this framework, the operator is susceptible to two classes of errors, viz., a *miss* (failure to notice a real signal), or a *false alarm* (apparent perception of a signal that did not actually occur). Here, the human is treated as a faulty signal detector. So far, the studies of human reliability attempted to utilize indicators based on probability theory that had been elaborated in the field of technical sciences. These necessitate, as a prerequisite, knowing certain quantities that characterize human work, such as: (1) mean time between failures, (2) total number of errors made in a given length of time, (3) percentage of correctly performed tasks in a given length of time. The main quantitative indicators of human reliability are those of: faultlessness, readiness, restitution and relevance (temporal adequacy of operator's actions) (Ratajczyk, 1988). When determining human reliability for a given workstation, it is necessary to take into account those indicators that have the greatest impact on achieving the goal set for the operator.

A human component of a system is unique in that, on the one hand, it is error-prone, and on the other, it is capable of learning, gaining experience and becoming skillful. By all means a desired feature of a technical object is its ability of consistent, error-free operation, which guarantees certain stability; nevertheless, such an object does not display adaptability (i.e., it does not learn). The reliability of a system is influenced, in a multitude of ways, by the qualities of both the human and technical object that comprise it. Industrial practice so far has a better track record of correcting the qualities of technical objects rather than humans (Ignac-Nowicka, Gembalska-Kwiecień, 2014).

Contemporary research lines in reliability theory

Reliability theory is a field whose paradigms draw from two branches of mathematics: probability theory and statistics (Wilson, Limnios, Keller-McNulty, Armijo, 2005). The common feature of human reliability and that of other objects is the necessity to determine certain requirements (expectations). A significant difference between the concepts of human reliability and that of other objects is the possibility of interaction between the agent stating the requirements and the agent implementing them, i.e., the possibility of exchanging information about the states of the object itself, the human operator, and the environment. In modern science, the concept of reliability is given extraordinary importance due to its integrating properties, which enable synthesizing knowledge concerning a wide gamut of objects, whether technical or biological (Ignac-Nowicka, Gembalska-Kwiecień, 2014). This, in turn, facilitates making analogies and generating novel research hypotheses with the aim of answering new, continually arising practical problems that demand theoretical research.

According to the IEC 1069 standard, reliability is understood as the dependability of action and perceived two-fold: as a property described in probabilistic terms (through random events and processes), or in deterministic terms. The diagram depicting the relevant hierarchy is shown in Fig. 1.

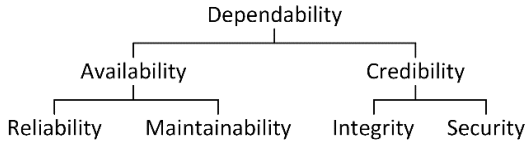

Figure 1: Hierarchy of terms according to the IEC 1069 standard

Source: (IEC 1069, 1991)

Object operational readiness and the associated reliability and maintainability are defined in probabilistic terms. The chosen facets of reliability understood as a property of the system as a whole are typically described using the following criteria: credibility, integrity and security (Bukowski, 2002).

A thorough analysis of state of the art on reliability was carried out by Ushakov (2006). Apart from the "classical" aspects of quality and reliability control in mass production, and the problems of structure modeling and object maintenance, Ushakov (2012) identified the following lines of research as worth pursuing:

- analysis of effectiveness and of the ability of objects to continue to function properly in the face of non-catastrophic damage;
- modeling object survivability in the presence of unforeseen disruption, such as internal system errors, the influence of the environment, or undesired human actions; in general, this creates a counter direction for analysis, and presents studies of vulnerability to damage/disruption;
- problems of modeling, studying and managing human and environmental safety following object damage, as well as object security from unauthorized access and interference;
- Software reliability in the presence of difficulties associated with the validity of basic assumptions of "classical" reliability theory: the stochastic nature of failure, the likelihood of failure as a function of time, the assumption that disruptions are independent events.

New challenges arise in the analysis and evaluation of reliability of, for instance: singular (unique) objects or systems whose resilience to damage is particularly high, global systems, information and communication networks, developing systems, delivery systems for replaceable parts, systems capable of tolerating transient failures, estimates of future operation costs and warranty period lengths, modeling of systems with guaranteed continual reliability and multi-state systems, accelerated reliability tests or synthesis of data from maintenance research (Nowakowski, 2011).

Vulnerability to disruption in a control system for executing production projects

By contrasting reliability with vulnerability to disruption, we assumed that reliability in a control system for executing production projects is tantamount to achieving a high ratio of correctly executed tasks. This, in turn, involves: maintaining performance, availability, high resilience (robustness, stability), required flexibility and tolerance to varying conditions, attained through appropriate checks against potential system disruptions. A system vulnerable to disruption is characterized by a low ratio of correctly executed tasks as a result of: the inability to maintain performance, insufficient availability, intolerance of certain conditions due to the lack of appropriate checks, inadequate resilience and flexibility. A disruption-tolerant system, in contrast, is characterized by a high ratio of correctly executed tasks owing to its ability to maintain performance, high availability, tolerance of conditions attained through appropriate checks, high resilience (robustness) and flexibility.

Information on the course of a process in a production system allows to identify possible operation and reliability states of this system and to determine the rules governing their transitions, which in turn has a significant impact on the execution of production tasks. At the same time, this facilitates the proper design of a support system for maintaining reliability and fine-tuning the subsystems of use and support. Therefore, it becomes necessary to define the supportability of a production system. Supportability can be identified as the ability of a production system, attained by appropriate organization of processes, production and logistical infrastructure, to ensure the appropriate level of availability under the assumed requirements/conditions of use (Nowakowski, 2011).

In this context, two basic concepts related to the reliability states of a control system for executing production projects can be identified: a system is either fit for the execution of required tasks, or it is unfit, the latter potentially leading to:

- disruption of, or failure to commence, the execution of the production task at hand,
- inability to commence the execution of subsequent production tasks.

Taking into account the unreliability state of a control system for executing production projects yields a new perspective on the efficient and effective functioning of a production system. This requires analyzing the capabilities of a logistical system for executing specific tasks, under specific conditions and at a specific time, when a new production project is entered into the system at random.

Disruption is defined as a violation of an established order or course of events, as disorganization. The term originates from the verb “to disrupt, i.e., to cause disruptions, disturb work or functioning of something”. Disruption of a project driven order was defined as the occurrence of an obstacle during the execution phase of a production project, such that it invalidates its original plan (standard). Santarek and Strzelczak (1989) distinguished two classes of disruptions: (1) those related to the production system, (2) those related to the environment. Relying solely on this classification is insufficient for determining appropriate responses to disruptions arising during project execution. It is the effect caused by a given disruption in the process rather than the disruption itself that is significant for a project execution coordinator. For instance, a delay in the execution of any non-critical action must not exceed the buffer time allocated for the given action if side effects for the timely execution of the project are to be avoided. Exhausting all buffer time, or not meeting the deadline for the execution of a critical action will in all probability deregulate the schedule, possibly invalidating the resource plan, and violating the expenditure plan .

The subject of analyses is a job-shop production system for a multi-project environment. In the production system for each task there is a mapping of machines to operations, and the required order of operations is specified. In the project approach machines (production stations) are allocated to actions and the ordering of actions in the project is specified. According to the nomenclature used in the project approach, an action is defined as the execution of work by a human-object technical system. The ordering of workloads performed by individual systems is determined by technological

limitations. Each action has its associated execution time, which includes the time required to prepare the station for the execution of a given action, and to subsequently return the station to its previous state (set-up time); and the time of transport between production stations.

In addition to a classification of disruptions our studies on the impact of disruptions on the course of a project driven order in a production system require a suitable model of the course of project execution. This model takes into account the structure of a production system, including production stations and production projects intended for execution. The representation of the course of production and the method of expressing the standard plan in the form of a schedule and its elements: the plan of expenditures, resources and costs, were also defined in the model. The methods of network planning are the basis for generating variants of the plan. We focused on these methods due to their utilitarian character and easy implementation. We also considered employing alternative approaches, such as Petri nets or the comparable, for a large body of problems, Karp-Miller-Rosenberg (KMR) algorithm. We rejected these methods on practical grounds – the aim is a rapid response to disruption, which is possible only when using data that have been entered into the system in advance, and pre-elaborated using a chosen method. The methods commonly used in industrial practice to dynamically obtain alternative plans for project driven orders are network planning and scheduling with priority rules.

Taking disruptions into consideration when modifying the project execution plan requires identifying its significant parameters. Each disruption is located both in space and time, and delineated by two events: its occurrence and resolution (Fig. 2). Both events can influence the course of project execution.

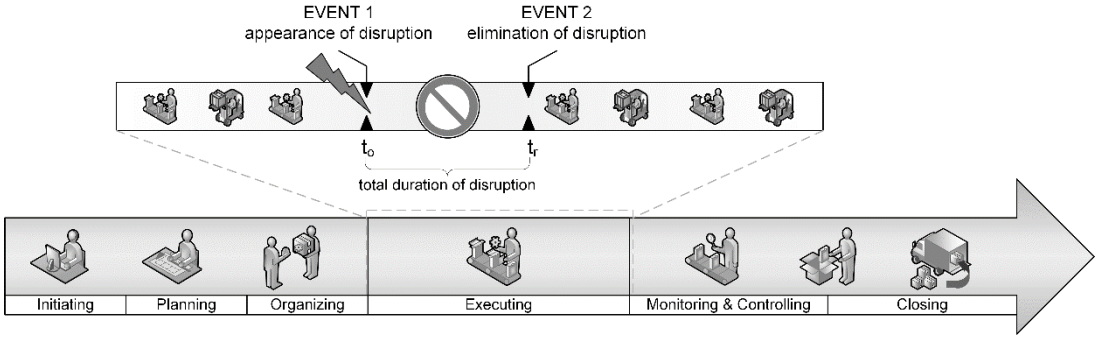

Figure 2: Description of a disruption

Source: own elaboration

The classification of disruptions *Ds* along with their impact on the elements of the main plan were presented in (Łapuńka, 2010). Times t_o and t_r are, respectively, the time of occurrence and the time of resolution, while the difference $t_r - t_o$ is the total duration of the disruption.

Adapting reliability theory to a control system for executing production projects

Controlling processes in real time during the execution of complex project driven orders creates a connection between the human, machines and technological devices, defined by their mutual interdependence. The issues of human reliability have become an integral part of reliability theory for systems, whose rhetoric in contemporary science is expressed by a continual search for contact points.

The concept of reliability in control systems for executing production projects requires, *inter alia*, changing the approach to the way of defining a system. To date, studies on the reliability of technical systems were dominated by a material approach, where a technical system is understood as a set of technical elements whose purpose is to execute a certain task. However, tasks set for a control system for executing production projects are more complex. The quality and reliability of the execution of a

project driven order are evaluated based on the degree to which several criteria, including customer's requirements, are met. Therefore, the task approach appears to be more suited for the analyzed problem. Then, the assessment of the correctness of the execution of individual tasks allows judging the quality and reliability of the entire control system. The concept of system reliability indicates the need to ensure the continuity of execution of the maintenance and operation process, as well as the relationships between the analyzed concepts, such as: reliability, readiness, and risk (Fig. 3).

Modern, comprehensive control systems and management systems for production enterprises leverage a multilevel and multilayered structure in order to increase the efficiency of decision processes. The physical structure of an organization, with units of decreasing size nested within units of a higher level, is reflected in the hierarchical structure of decision levels. Each decision element of a given project perceives only selected elements of a subordinate level, and directs its control decisions to these elements. Therefore, at each level the problem of efficient control is restricted to elements on the immediate subordinate level, in line with the strategy elaborated in advance. Control decisions directed to the lower level will depend on the planning horizon established at the decision level, on the need for production in this horizon, the processing capacity of lower-level elements, the ability to obtain usable energy, resources, knowledge and engineer cadre. The indicator of the quality of functioning of a given level should be similar across levels. This indicator should be tied to the maximization of profit from the execution of the production that is obtained at a given level and within the considered time horizon, taking into account the baselines established for this level (e.g., resources, standards, technologies). Lower-lying levels are characterized by an increasingly shortening planning (control) horizon, more accurate models, based on which strategy is selected, increased frequency of disruption and, therefore, of (control) interventions (Klemiato, Augustyn, Duda, Sterna, 2011).

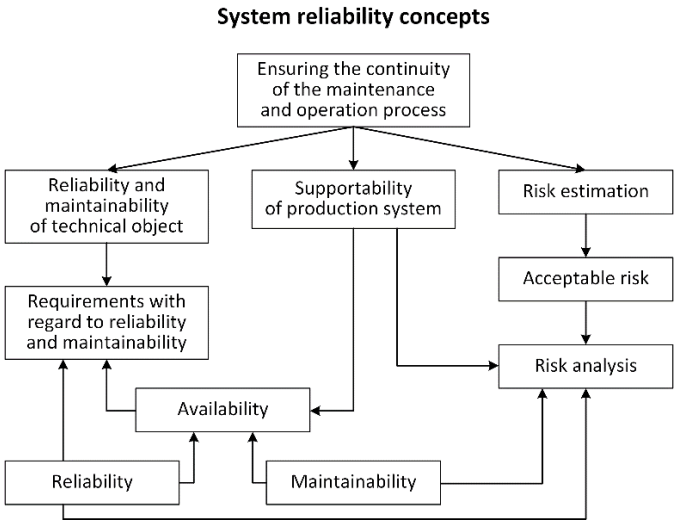

Figure3: Requirements of execution of tasks in the operation of a control system for production projects

Source: elaboration based on (Nowakowski, 2011)

The lower the level, the easier it becomes to automate it, that is, to replace a human (operator) with smart devices and logic controllers. At higher levels the use of computers is mostly restricted to computer-aided decision-making. In such a structure, a top-down decision flow with a depth of one level is maintained, with a bottom-up flow of feedback on the execution of tasks, similarly restricted to one level. Such feedback should first take the form of measurement signals, then periodic reports at a higher level, and finally – of summary reports.

Measurement signals are weak or faint signals, also known as early warnings, early indicators or early symptoms. They are used in corrective actions taken during the execution of a project (Pisz, Łapuńka, 2015). They can be a valuable source of information about potential changes, which is particularly important in the operation of flexible production systems and dynamic organizations. It is necessary to continually monitor symptoms of changes, as with time an increasing number of signals can indicate a change in the environment of an enterprise or in the project itself. Monitoring such indicators can aid the early detection of a crisis (e.g., the occurrence of a particular disruption) or the threat of it occurring. It must be noted that early warning indicators can be tied to specific risks, or areas where certain problems are expected to occur. Weak signals are obtained, gathered and processed by early warning systems. These systems secure planning and control processes in terms of information by delivering information that can potentially reduce decision uncertainty. In so doing, they improve the rationality of decisions made during the execution of project driven orders.

Recently, researchers have shown increased interest in the application of weak signals in the control of project execution (Nikander, Eloranta, 2001; Vanhoucke, 2011). Nikander and Eloranta (2001) presented a classification of weak signals identified in construction projects, obtained through surveys conducted among project managers. Sets (tables) of indicators in the form of project dashboards, which enable monitoring the project at hand in order to rapidly implement corrective actions (Kerzner, 2013), enjoy a rise in popularity. Project dashboard is a type of a dynamic report whose main elements are graphical indicators. These indicators can signal the current status of project execution, the risk level, the level of remaining buffers (tolerances) built into the structure of project control, as well as providing key performance indicators (KPI). An example template is shown in Fig. 4.

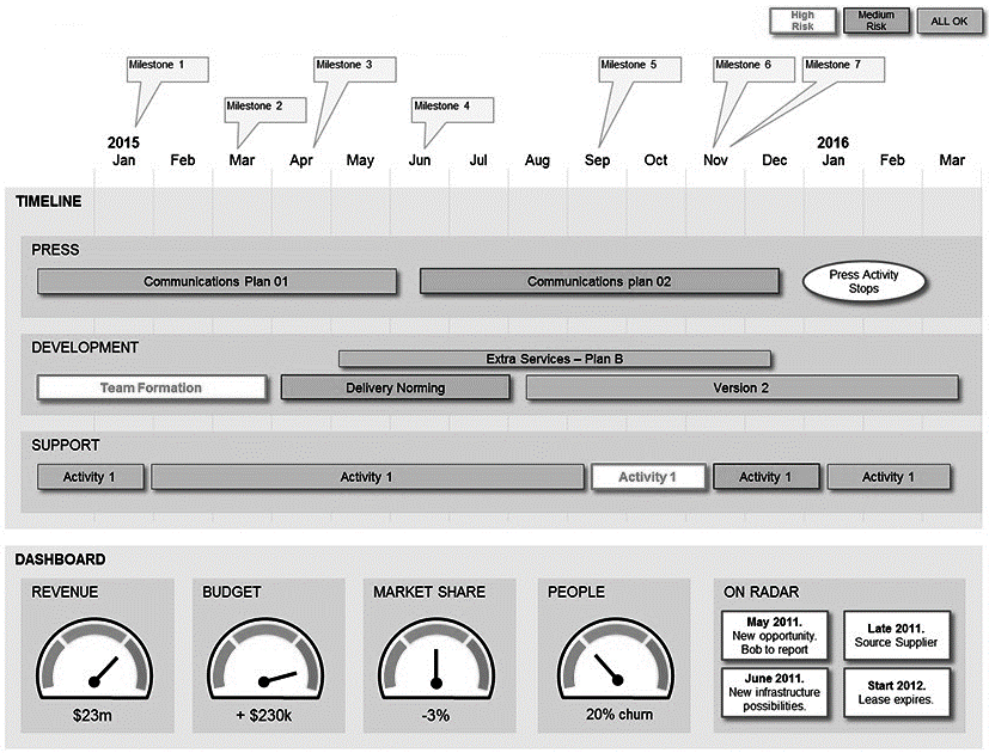

Figure 4: Project dashboard template with a project roadmap and a set of KPIs

Source: [https://business-docs.co.uk]

Project dashboard templates can also take the form of summaries of critical information on projects in the project portfolio (Fig. 5).

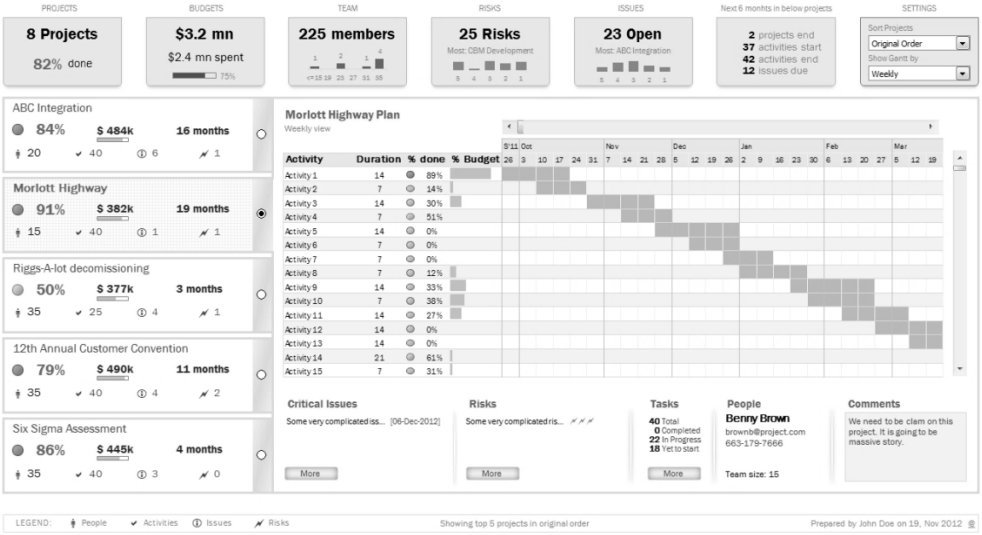

Figure 5: Project dashboard template for a project portfolio

Conclusions and future research directions

Flexibility and changeability are integral parts of modern market economy. The conditions of a turbulent and hypercompetitive environment force the majority of enterprises to undertake unique orders, often encountering serious obstacles to their proper execution. The elaboration of a multidimensional reliability concept in a dynamic control structure for executing production projects and implementing it in the form of an early warning computer system could significantly increase the efficiency and effectiveness of managing production projects. Early warning systems constitute a specific kind of information systems for an enterprise, with a main goal of directing the executed processes towards perceiving and interpreting weak signals (Nalepka, Bąk, 2012).

By contrasting reliability with vulnerability to disruption, we assumed that reliability in a control system for executing production projects is tantamount to achieving a high ratio of correctly executed tasks, which can be expressed by maintaining performance, availability, high resilience (robustness, stability), required flexibility and tolerance to varying conditions, attained through appropriate checks against potential system disruptions.

In the framework of a multilevel control system, the integration of enterprise resource planning (ERP) information systems with manufacturing execution systems (MES) is assumed. The MES functionality, apart from advanced planning and scheduling (APS) of production will also include managing project scope and course, production reporting, providing KPIs, managing changes (disruptions), monitoring order status and deliverables, and managing material and human resources. Project dashboard templates with a set of indicators and a graphical representation of the progress of execution, i.e., a project roadmap, will supplement this structure. Along with the application of EVM and SRA, we will employ alternative approaches to project monitoring, viz. the top-down approach in the case of SRA, and the bottom-up approach in the case of EVM. Information obtained in this way will play the role of weak signals for corrective actions taken during the execution of the project, and provide knowledge about the remaining buffers (tolerances) built into the structure of a multilevel project control system.

The dual nature of analysis of vulnerability to disruption and modeling the resilience of a system to unpredictable effects, e.g., to system internal errors, undesirable human actions or the impact of environment, constitutes a complementary approach to controlling the execution of production projects and sets directions for future studies.

Abstract

Accommodation establishments belong to the basic facilities of tourism infrastructure because they allow visitors to stay in the visited area. The main aim of this paper is to locate all individual and collective accommodation establishments in the studied area. The studied area is defined as the regions of South Bohemia and the Bohemian Forest because these regions belong to the most important areas for tourism. Through the cartographic visualisation, specific spatial disparities in location of various categories of accommodation establishments (hotels, boarding houses, campsites, tourists' hostels and other accommodation establishments) were revealed. The contribution of this paper lies in the undertaken analyses of the location of each accommodation establishment in the studied area – the Czech Statistical Office does not provide this comprehensive view.

Keywords: accommodation establishments; localization; cartographic analysis; Czech Republic

Introduction

A developed tourism infrastructure, including accommodation establishments, is a necessary condition for the development of tourism. The existence of accommodation establishments and their standard of services are very important factors, influencing the length of stay of tourists in the visited area. There is a number of relations between tourism and accommodation (Palatková, 2006); these relations are expressed by various models, however, all models have their weaknesses (Horner and Swarbrooke, 2003). Tourism in relation to the accommodation serves as a source of demand for accommodation, catering and other services related to them (Gúčik and Patúš, 2005). Some postulations claim the accommodation sector belongs to the sphere of ensuring tourism (Kašpar, 2011). Accommodation establishments belong to the basic facilities of tourism infrastructure because they allow visitors to stay in the visited area (Mariot, 1983) and they form the basis for further development of the destination (Goeldner and Ritchie, 2009). Ritchie and Crouch (2003) consider the accommodation establishments as one of the sources of destination's competitiveness. Goeldner and Ritchie (2009) agree with this opinion and they state that building accommodation capacities is one of the essential elements of the development of tourism in destinations.

Accommodation establishments belong to the tourism enterprises which are defined as business entities that meet the needs of end users and that carry out their business activities independently and on their own account by taking over an adequate entrepreneurial risk (Gúčik, 2000). Beránek and Kotek (2007) claim tourism enterprises have various functions. In the basic functions of tourism enterprises, the following functions can be included: business function (using business opportunities in order to increase the value of the own capital), economic function (carrying out activities related to

the supply, manufacturing, sales, providing services), organizational function (the maximum possible utilization and appropriate internal organization of production factors and the relations between them), environmental function (it indicates the status and activities of the company in relation to its impact on environment quality and environmental protection), technical function (equipment with essential production factors and creating technical and technological conditions for company's activities) and social function (it represents not only the care of company's employees and the relationships between them, but also it is the impact of the tourism enterprises on economic and social development of municipalities, cities and regions) (Kutscherauer, 2007, Kučerová, Strašík and Šebová, 2010). Environmental function is recently given a bigger attention (e.g. Geerts, 2014) in close relation to the topic of the environmental impact of tourism and its sustainability (e.g. Juvan and Dolnicar, 2014; Navrátil et al., 2015; François-Lecompte Gentric and Audigier, 2013).

Tourism services are mainly the product of tourism enterprises. According to Hesková et al. (2011), services can be described as a heterogeneous set of useful effects, designed for satisfying the tourists' needs. A similar view can also be found in the foreign literature, e.g. Lipsey and Nakamura (2006). Services are cross-sectional, i.e. they are offered not only by tourism enterprises, but also by other subjects in the private and public sectors.

Accommodation services are provided in establishments that are appropriate for this purpose, i.e. equipped materially, technically and personally (Liška, 1997). Accommodation establishments are objects, spaces or areas where the accommodation services for public are provided (Stárek and Vaculka, 2008). For overnight stays, the accommodation means can be used – in addition to accommodation establishments (Orieška, 2010) – see endnote [1].

In accordance with the Decree of the Ministry of Regional Development of the Czech Republic (see endnote [2]), accommodation establishments are "buildings or their parts where the temporary accommodation and related services are provided for public; neither family or apartment houses nor buildings for individual recreation are accommodation establishments; accommodation establishments are divided into categories and according to the required space and equipment into classes, which are marked with stars". Čertík (2001) distinguishes between two types of accommodation:

a) accommodation in collective accommodation establishments (e.g. hotels),
b) private accommodation (in houses, cottages etc.). The private accommodation is provided in the so-called individual accommodation establishments (Ryglová, Burian and Vajčnerová, 2011). In practice, according to these authors, it is renting a residential room, a vacation apartment or a flat, a cottage or a weekend house.

The collective accommodation establishments are defined as establishments which provide accommodation services, e.g. hotels and other collective accommodation establishments, such as campsites, vacation villages, tourists' hostels (Beránek and Kotek, 2007). Some authors use the term "hotel" for collective accommodation establishments – for instance, Kiráľová (2006) considers a hotel as a public accommodation establishment that provides temporary accommodation and related services for money, all year long or seasonally (i.e. max 9 months in the year). From these definitions, inaccuracies in the interpretation of the terms hotel and accommodation establishments arise often.

According to the valid terminology, the term "collective accommodation establishments" is superior to the term "hotel". The Czech Statistical Office uses the term "collective accommodation establishments" in its researches(see endnote [3]). Accommodation establishments are distinguished according to types into categories and according to the level of provided services into classes. Many other authors consider this definition as a starting point (e.g. Indrová, 2008, Černý and Krupička, 2007, Smetana and Krátká, 2009, Křížek and Neufus, 2011, Ryglová, Burian and Vajčnerová, 2011). Institutions which are engaged in practice and research in tourism and accommodation services (for instance: the Czech Statistical Office, the Ministry of Regional Development of the Czech Republic, Czech Tourism Agency and other) use the above mentioned distinction between categories and

classes. This distinction appears also in the methodical materials which are used for classification of accommodation establishments.

The Czech Statistical Office deals also with the division of accommodation establishments – this Office regularly reports the number of establishments and beds. According to the methodological approach of the Czech Statistical Office, there are collective (see endnote [3]) and individual (see endnote [4]) accommodation establishments. The collective accommodation establishments are divided into hotels (with a different number of stars), boarding houses, vacation villages, tourists' hostels and other collective accommodation establishments such as recreational facilities of companies, training centres, cultural and historical buildings and other accommodation establishments offering bed capacity for tourists (e.g. youth hostels, student residences, company accommodation establishments etc.). In this paper, this division is valid because of using statistics by the Czech Statistical Office.

An efficient location is one of the fundamental decisions of every entrepreneur (Koráb, Peterka and Řezňáková, 2007). The basis for location of accommodation establishments is the occurrence of tourism attractions (Mariot, 1983) which are able to attract visitors (Ritchie and Crouch, 2003). Shoval, McKercher and Birenboim (2011) agree with this theory. The next important factor for localization is the opportunity to get benefits from the accumulation of economic activities (e.g. Head, Ries and Swenson, 1995, Johansson and Quigley, 2004). This accumulation determines creating spatial clusters of the accommodation establishments (Porter, 2000). The concentration of accommodation establishments is manifested through formation of spatial clusters; the character of these clusters is generally determined by the strategies of the individual accommodation establishments (Chung and Kalnins, 2001). However, generalization of these models is difficult and published results of such analyses are often mutually inconsistent (Kalnins and Chung, 2004, Urtasun and Gutiérrez, 2006). Loureiro and Kastenholz (2011) take notice of the fact that the accommodation establishments are not located only in large cities but also in the environment of rural villages. According to Walford (2001), nature and landscape are the main attractions for building accommodation establishments. Distribution of the accommodation establishments in in the towns and cities is significantly influenced by the distance of the historical center (Švec, R., Navrátil, J. and Pícha, 2014).

It goes mainly for hotels and hotel chains – in the past, the most attention was paid to them and hence, it was possible to identify several models of location of hotels in the urban environment (Bučeková, 2001).

From the theoretical and methodological point of view, the conditions of localization are divided into location because of the social-economic gravity and location because of the transport accessibility (Bégin, 2000, respectively Aliagaoglu, 2008). The first group includes locating to the historical centre of the city (usually it is the area between the historical centre and the business area) and to the attractive places. The second group includes location near transportation hubs, such as railway stations, the main streets in cities, roads which link cities and/or airports, bus stations and stops (simplified according to Aliagaoglu, 2008). For the area of the Central Europe, Bučeková (2001) defines also hotels located in large housing estates.

The mutual spatial links of locating accommodation establishments can be monitored on the basis of their geographical distance, offered price, their size and provided services (Urtasun and Gutiérrez, 2006, Navrátil and Navrátilová, 2011). Bučeková (2007) examines the process of the spatial deconcentration when the hotel establishments are located. Shoval and Cohen-Hattab (2001) deal also with this process and they state this process may be in relation to the shift of accommodation establishment to the edges of the city – this shift is made possible because of improving their accessibility caused by the development of suburbanization processes in big cities. Shoval (2006) confirms the link between the distance of the hotel to the city centre and the structure of hotel's visitors.

Aim and methods

The main aim of this paper is to locate all individual and collective accommodation establishments in the studied area (the reason for it is the fact the Czech Statistical Office does not provide any complete overview of accommodation establishments, respectively these data are considered to be confidential). There are also partial aims: to show the diversity of accommodation options in the studied area and to identify where these accommodation establishments are concentrated. It means the aim is to answer the question where the particular categories of accommodation establishments are located – within the regions of South Bohemia and the Bohemian Forest (in Czech language: "Šumava"). These regions belong to the most important areas for domestic tourism and because of their border position, they are attractive also for many foreign tourists.

In order to fulfil the aim, data were analysed to determine the total number of accommodation establishments and later these data were compared with reality through the field research. Because of the incompleteness of data from secondary sources (i.e. from the Czech Statistical Office), it was necessary to create a new database of accommodation establishments in the studied area. The individual accommodation establishments were identified on the Internet. In the database, accommodation establishments were recorded from these sources: the Czech Statistical Office, tourist information centres in the studied area, accommodation establishments listed on the websites of municipalities and accommodation establishments registered on special servers (namely http://www.penziony.cz/, http://www.ubytovani.cz, http://kamsi.cz/, http://www.nadovcu.cz, http://ubytovani.nettravel.cz/, http://www.hotel-ubytovani.com/ http://www.ubytovani.net/, http://www.levneubytovani.net, http://ubytovani.turistik.cz/, http//www.ubytovanivcr.cz, http.//www.ubytovani-cechy.cz, http://www.prespat.cz/, http://www.e-ubytovani.eu and http://www.tourism.cz/). Simultaneously, detailed tourists maps of the studied area were analysed – on these maps, accommodation establishments are usually also recorded (but there could be a problem with up-to-dateness of the data and this was the reason why before every record in the database, the existence of the individual accommodation establishments was verified via the Internet). The individual accommodation establishments were located by their addresses through Web Map Service (WMS) by Cenia agency (through the tools JANITOR J/2 and Quantum GIS) and also information about the number of beds and about the accommodation category were added. Subsequently, the identified categories of accommodation establishments were reduced in accordance with categories used by the Czech Statistical Office. In the studied area, accommodation establishments of all categories were identified and they were included in the further processing.

Studied area

From the administrative point of view, the studied area comprises of the South Bohemian Region and the district Klatovy (which belongs to the Pilsen Region) – see Fig. 1. In the following text, the term "studied area" is used.

The South Bohemian Region is the core of the studied area – this area can be characterised by a temperate climate and is located in the southern part of the Czech Republic along the border with Germany (Bavaria) and Austria (Upper Austria) (Cetkovský et al., 2007). The chosen area comprises two tourism marketing regions: South Bohemia and the Bohemian Forest (in the Czech language: "Šumava"), see Fig. 1. The territory extends throughout a rather geographically diversified part of the Czech Republic. Bohemian Forest National Park (in the Czech language: "Národní park Šumava"), the Třeboň Protected Landscape Area (in the Czech language: "Chráněná krajinná oblast Třeboňsko"), the Bohemian Forest Protected Landscape Area (in the Czech language: "Chráněná krajinná oblast Šumava"), and the Blanský Forest Protected Area (in the Czech language: "Chráněná krajinná oblast Blanský les") are the largest conservation areas in the studied area (Navrátil et al., 2012, Navrátil et al., 2014).

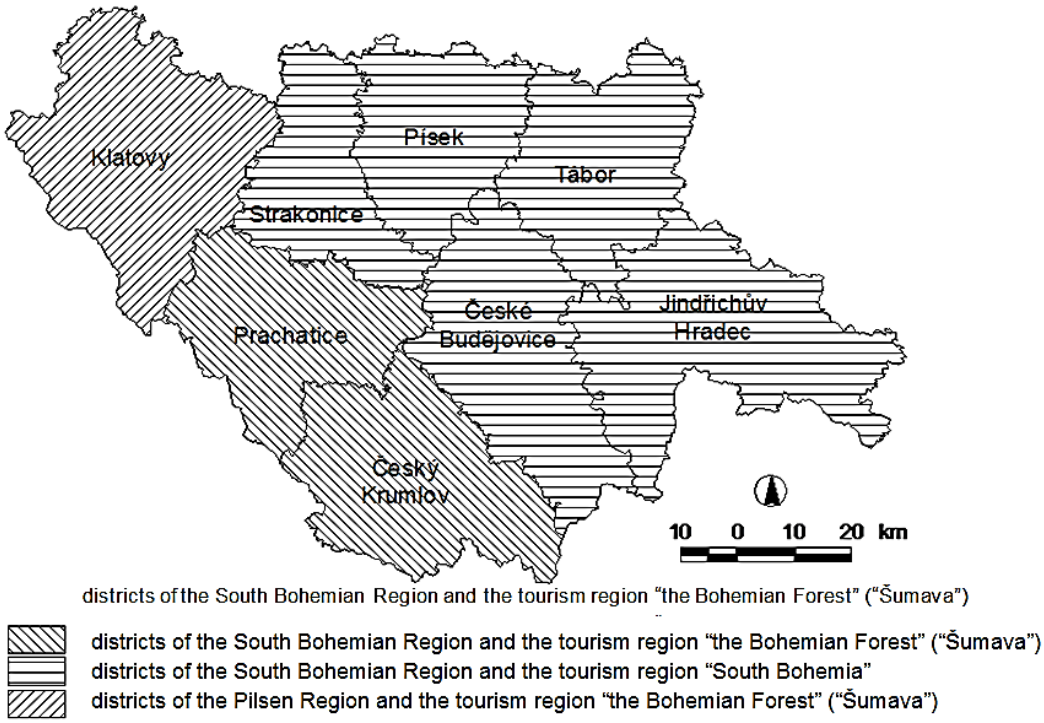

Figure1: Administrative structure of the studied area

Source: Map material by the Czech Statistical Office (ČSÚ, 2015), own processing (by the first author of this paper).

Results

In the studied area, there is a relatively high proportion of the total number of accommodation establishments in the Czech Republic: it is 13.3 % of all accommodation establishments (ČSÚ, 2015). The increase of the number of accommodation establishments was distinct in the period 2000-2004, a slight decrease was in 2005 and further growth in the period up to 2007. In 2008, the number of the accommodation establishments started to diminish. This trend stopped in 2011 – there was an increase in the number of the accommodation establishments mainly in the South Bohemian Region. In general, it can be said the number of the accommodation establishments grew in the studied area in the period 2000-2012. Fig. 2 presents the situation in recent years. The methodological approach was revised in 2012 and that is why the Czech Statistical Office does not show a longer time series – more accommodation establishments have been included so the data for the year 2012 and the continuation of the time series diverge (compare Fig. 2 and Fig. 3).

The cartographic analysis shows the location of the individual categories of accommodation establishments in municipalities which are a part of the studied area. The focal points of the geographical concentration for each category differ quite significantly (see Fig. 4-8).

Bed capacities of the hotel accommodation establishments (Fig. 4) are located mainly in the larger cities of the studied area (such as České Budějovice, Tábor, Písek and Klatovy) and also in places which have significant localization assumptions for tourism. Other localities are cities offering cultural and historical attractions such as Český Krumlov, Hluboká nad Vltavou, Třeboň and localities offering opportunities for sport and recreational tourism – mainly mountain resorts in the Bohemian Forest (Šumava – Železnorudsko and Kašpersko).

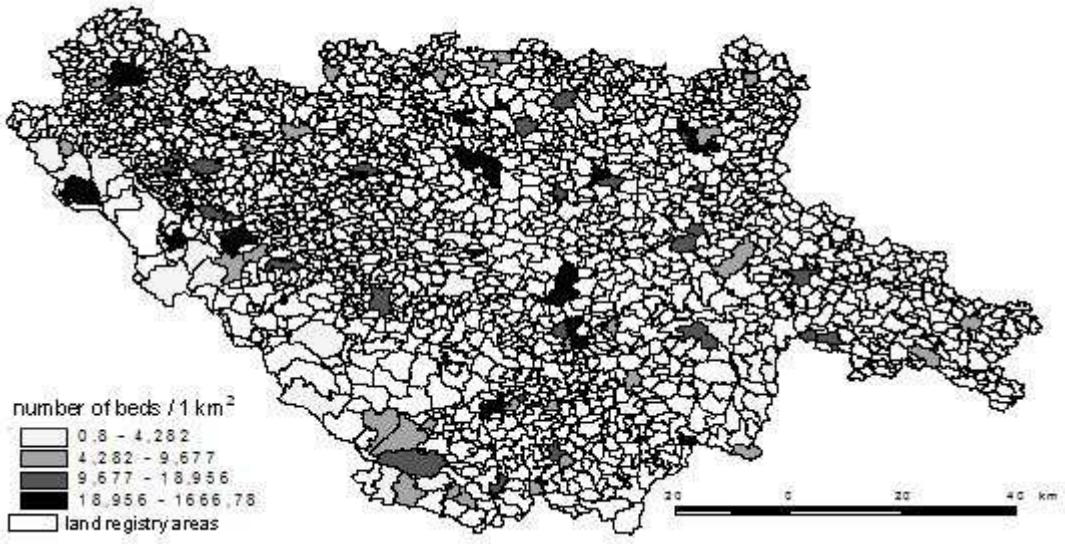

Figure 4: Number of beds in hotels located in municipalities in the studied area
Source: Own processing (by the first author of this paper).

Fig. 5 presents bed capacities of the boarding house accommodation establishments. According to the research findings, the number of beds in this category is strongly tied by natural localization assumptions. Bed capacities are located primarily in the Bohemian Forest (mainly Železnorudsko, locality of Kašperské Hory and Lipno) and also in the locality of Třeboň and Třeboňsko. Furthermore, boarding houses are located close to places with a big concentration of tourists. On the basis of own assumptions, the localization of boarding houses near the major cities was expected, however, this assumption was not confirmed.

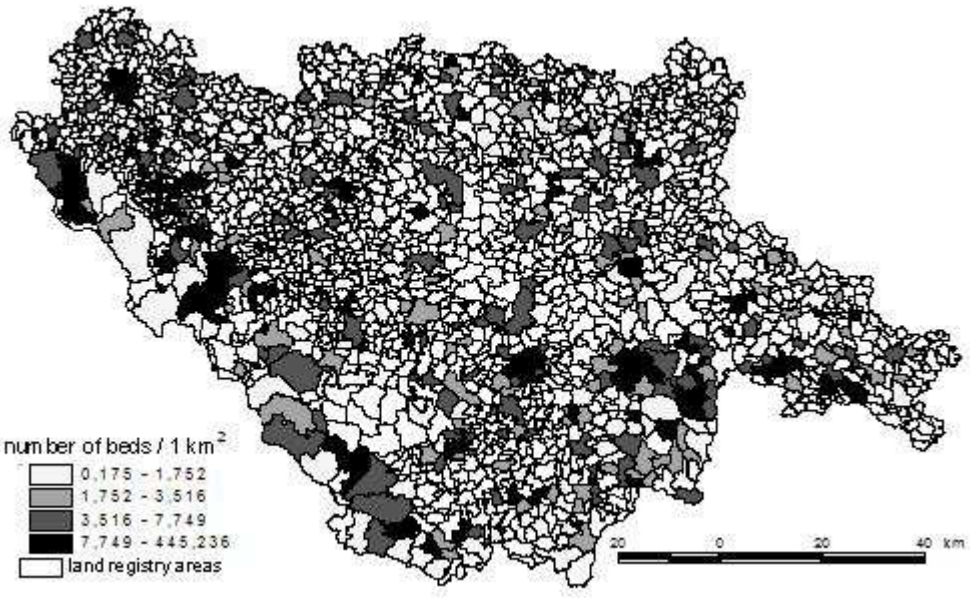

Figure 5: Number of beds in boarding houses located in municipalities in the studied area

Source: Own processing (by the first author of this paper).

Location of the campsites differs considerably from the locations of hotels and boarding houses. At first glance, it does not arise any significant spatial relations from the campsites location (see Fig. 6). However, closed examination reveals certain relations. In the cartogram (Fig. 6), there are clearly evident curves of rivers Otava and Lužnice which are attractive for the segment of boating tourists (boating tourism is a favourite kind of tourism in the Czech Republic). Besides the curves of the above mentioned rivers, other localities like the eastern Třeboňsko (where are recreational ponds and sandpits) and dams like Lipno and Orlík are localities with campsites. It means, campsites are tied by the presence of banks of watercourses and bodies of water.

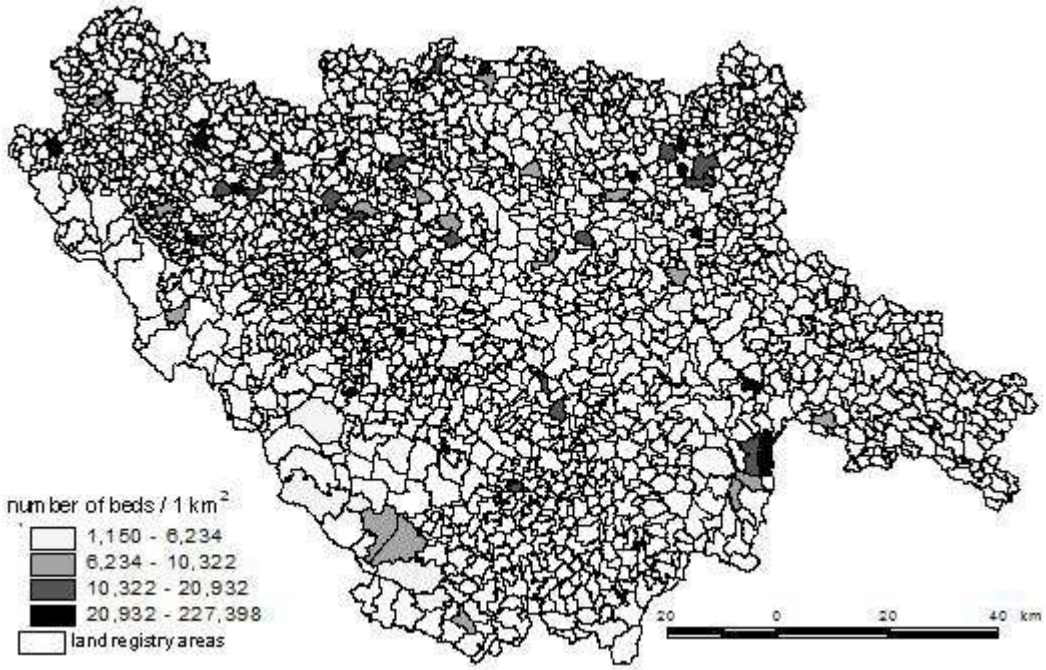

Figure 6: Number of beds in campsites located in municipalities in the studied area

Source: Own processing (by the first author of this paper).

In the studied area, a low number of tourists' hostels was identified. Despite this, it is possible to specify a certain similarity to the location of hotels – tourists' hostels are located primarily in cities and larger towns such as České Budějovice, Jindřichův Hradec, Třeboň, Tábor and Strakonice (see Fig. 7).

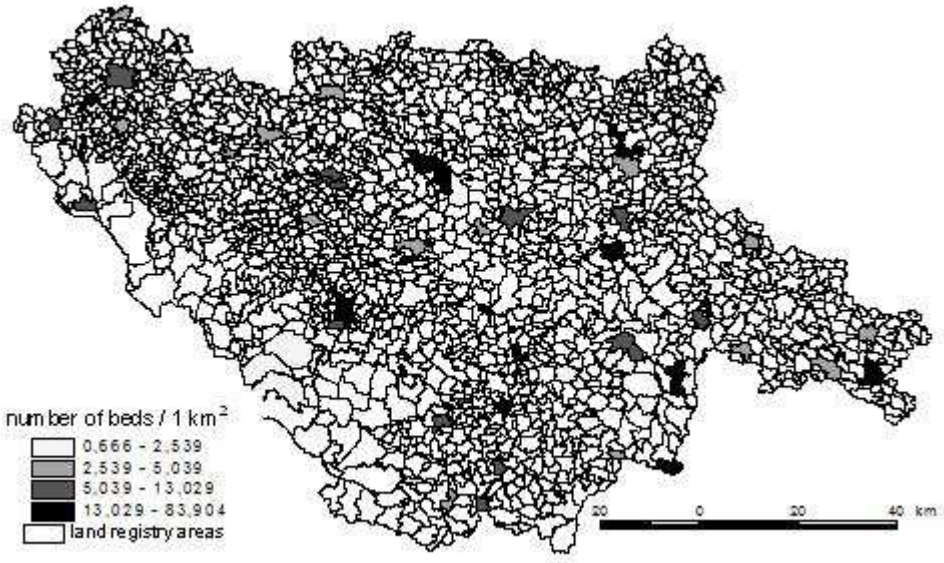

Figure7: Number of beds in tourists' hostels located in municipalities in the studied area

Source: Own processing (by the first author of this paper).

Lower numbers of bed capacities wre also identified for other accommodation establishments. These establishments are located primarily in two localities – in the south part of the Orlík dam and in the locality of Třeboňsko (see Fig. 8).

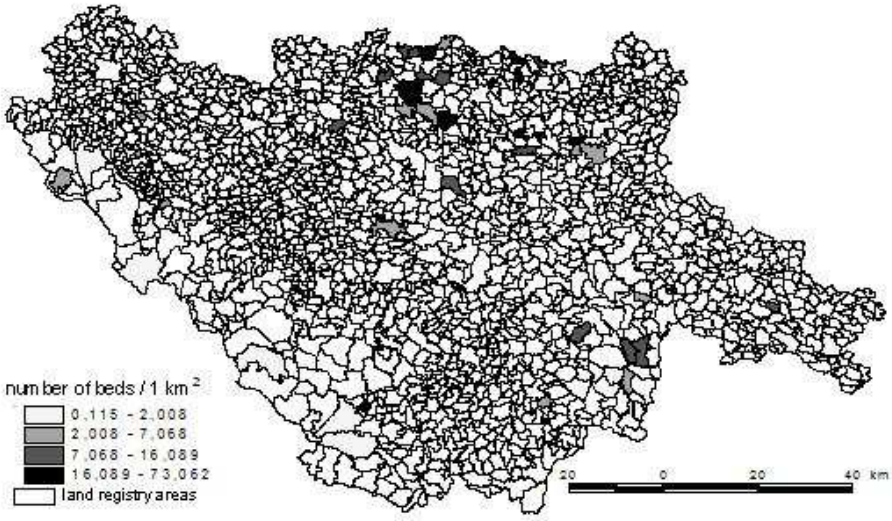

Figure8: Number of beds in other accommodation establishments located in municipalities in the studied area

Source: Own processing (by the first author of this paper).

In the studied area, accommodation services have a long history. Currently, the studied area is the first in the proportion of the total number of accommodation establishments in the Czech Republic.

Conclusion

The infrastructure of accommodation, catering and other services is historically dependent on the traditional demand for the natural and social attractive places, e.g. the Bohemian Forest ("Šumava"); South Bohemian ponds; Lipno dam, Orlík dam; rivers Vltava, Lužnice, Otava; cities with castles like Hluboká, Český Krumlov, Orlík and Zvíkov (Šíp and Klufová, 2003).

Through the cartographic visualisation, specific spatial disparities in location of various categories of accommodation establishments were revealed. According to the findings, hotels are primarily concentrated in larger towns or in places with extraordinary potential for tourism (e.g. for winter sports). Boarding houses are mostly located in localities with appropriate natural conditions whereas their low concentration was found out in larger cities (České Budějovice, Český Krumlov). Location of tourists' hostels corresponds to the location of hotels that are almost exclusively tied by the cities. Further it was found out that campsites are located mainly near watercourses and bodies of water. The category of other accommodation establishments shows also a significantly specific concentration – they are located near bodies of water.

The contribution of this paper lies in the undertaken analyses of the location of each accommodation establishment in the studied area – the Czech Statistical Office does not provide this comprehensive view. The findings can serve as a basis for future research which will be focused e.g. on spatial relations because of the attractiveness of the individual localities or the findings can be a starting material for working out a map of price levels in the accommodation establishments according to the attractiveness of individual localities in the studied area.

Endnotes

[1] Accommodation means = tent, caravan, boat, ship etc. (Orieška, 2010).

[2] Decree No. 268/2009 Coll. on the technical requirements for buildings (see References: Vyhláška č. 268/2009 Sb. o technických požadavcích na stavby).

[3] The collective accommodation establishment is „an establishment with at least five rooms and ten beds used for the purpose of tourism that is offering temporary accommodation to guests (including children) for the purpose of a holiday, trip, spa treatment, business trip, training, course, congress, symposium, children's school in nature, summer and winter children camps, etc." (ČSÚ, 2009).

[4] Accommodation establishments with lower capacity than it is the minimum for the collective accommodation establishments are classified in the category of the individual accommodation establishments. The Czech Statistical Office has not followed them since 2002. These establishments include rented rooms, flats, cottages and accommodation at family farms (in accordance with the agrotourism).

Abstract

The current study investigates the speed toward target capital structure and dividend policy of family owned business (FOB) versus non-family owned Business (NFOB). For the identification of FOBs from NFOBs, two threshold levels of ownership (25% & 50%) were applied. For this purpose, panel data ranging from the period of 2002 to 2013, a sample of 280 listed firms at Karachi Stock Exchange (KSE) were used. Among many the generalized method of moments (GMM) was found appropriate as an analytical technique. The result drawn through GMM indicated that FOBs rebalance their target capital structure with higher average speed (38.70%) than NFOBs. However, the average speeds toward target dividend ratio were (63.05% & 71.05%) for FOBs and NFOBs.

Keywords: Family Business; GMM; Speed; Target capital ratio; Target dividend ratio

1.0 Introduction

The main objectives of the current study were to analyze the speed toward target capital structure and target dividend ratio in terms of FOBs and NFOBs. Since the seminal work of Modigliani and Miller (1958), the capital structure was the hot topic and had been a source of great attraction for research scholars and authors. A large number of recent studies like (e.g. see Frank and Goyal, 2009 and Denis and Osobov, 2008) have explored the factors influencing the debt and dividend policies. But the studies focus on the dynamics of target capital structure and dividend policies in relation with ownership are yet scarce. The present study aims to fulfill the gap in existing literature of finance.

A series of financial models and theoretical framework has been developed to explore the determinants of dividend policy along with debt policy that ultimately affect the corporate value of firms. Among them the most important are pecking order and trade-off theories (Myers and Majluf, 1984) which provide the explanations regarding determining the target capital structure and dividend policy of firms. The main objective of both capital structure theories is to explain the factors that

contribute the financial decisions of a firm. Lintner's outcome model (1956) provided the explanations for the reasons behind stable dividend policy and argued that managers are reluctant to cut dividend payments as it might have adverse effect of stock price; consequently, the company's dividend remain stable over time especially in case of family business.

The trade-off and pecking order theories need to be considered mutually exclusive. De Haan et al. (1994) highlighted in Netherland's study that most of the companies follow pecking order theory during rebalancing their capital structure. De Haan and Hinloopen (2003) found that the both theories have empirical importance when adjusting their capital structure's choices. Furthermore, other empirical evidences showed importance of pecking order theory in the short term and trade-off theory in the long run (Hovakimian et al., 2001; Kayhan and Titman, 2004; Mayer and Sussman, 2004). Companies having low level of debt unlikely to adjust their capital structure immediately but they increase the leverage after exhausting all available internal fund. Similarly, the companies having higher level of debt likely to decrease it through increasing equity (retained earnings); rather than immediately rebalancing capital structure. Titman and Tsyplakov (2004) proposed a dynamic model in which value of business was endogenously estimated by financial decisions. They revealed that the pecking order behavior influences target capital structure and companies also move towards a moving target leverage, which is determined by trade-off considerations. Several firms' level specific characteristics play an important role in dividend smoothening and provide explanations regarding agency and dividend signaling theories. Thus, the absence and presence of the factors explain significant difference in readjust the dividend policy. The current study aims to explain the dynamic nature of financing behavior of companies.

1.1 Definition of family firm

A firm is said to be family owned business (FOB) if family directors have managerial ownership or voting rights 25% and 50%. 25% cut off point is proposed in the official definition of GEEF by its French name. This cutoff point is also in line with the definition adopted by Board of Family Business Network in April 7, 2008. 50% cut off point is used because ownership at this level confers the unequivocal control rights (Doidge et al., 2005). Also, particularly in Pakistan, owners of family companies like to hold more than 50% shareholdings (Attiya and Robina, 2010).

1.2 Objectives of study:

- To determine the speed toward target capital structure of FOBs and NFOBs.
- To analyze the speed toward target dividend policy of FOBs and NFOBs
- To make some recommendations regarding debt and dividend policies of each category of business.

2.0 Review of Literature and Hypotheses Formulation:

Target capital structure another important feature for every organization, the speed of adjustment toward the target capital depends upon financing decisions of the company. The previous literature of finance showed a few studies that are available to explain how financial characteristics of firms that have impact the adjustment of speed toward target capital structure. Furthermore, information regarding speed toward target debt level helps the firms to rebalance their capital structure adequately. The current study aims to fill the gap in family literature by analyzing the impact of ownership on the adjustment of speed toward target capital structure. Öztekin & Flannery (2009) showed through empirical evidences that the firms with better governance and lesser agency problems rapidly approach toward target capital structure. In family firms, due to lesser agency problem and lower level of information asymmetric problem leads to higher speed toward their target capital structure.

Firms that undergo severe agency conflicts may try to smooth dividends payout to alleviate such concerns of different types of shareholders. On the contrary, in those firms where exist less severe

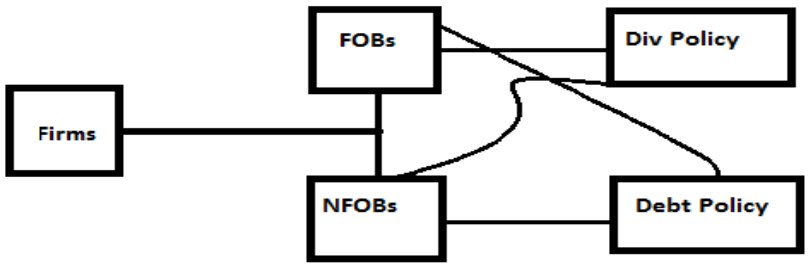
conflicts of interest and asymmetric information (family owned firms) tend to smooth amount of dividend payments to lesser extent. Michaely, R., and Roberts, M.R. (2006) opined that the firms with the least severe information and agency conflicts are less likely to alter their dividend policy and therefore, less likely to smooth dividends. As the family firms being fewer constraints than non-family firms, hence, they are less likely to change their dividend policy.

S.H.Tahir et al. (2016) examined both dividends as well as debt policies in term of family and non-family businesses. They applied two cut off points (12% & 50%) for distinguishing non-family firms from family business. They used panel data sample ranging from 2002-2013 of 280 listed companies at Karachi Stock Exchange (KSE) and applied Generalized Methods of moments to estimate the coefficients of variables. The empirical results provided explanation regarding speedier rebalancing the target capital structure of family firms due to easier access to debt and long term presence of the family in the firm. However, FOBs smooth dividends to lesser extent than their counterpart NFOBs indicate lower agency and information asymmetry problems in them. S.H.Tahir & H.M. Sabir (2014) revealed that family companies alleviated financial constraints along with free cash flow problems.

A. Getzmann et al. (2014) studied the capital structure of Asian firms and found different from US companies in term of financing decisions. They tested the relation between trade of theory and pecking order theory. They analyzed the speed of adjustment toward capital structures for 1239 firms with capitalizations of more than US$1 billion listed on 11 Asian stock exchanges and belonging to eight industrial sectors through generalized method of moments (GMM). They concluded pecking order theory superior explanatory power over tradeoff theory. Furthermore, they concluded that annual adjustment speed of 24–45% of original leverage levels and influenced by fixed effects.

The main objective of this study is to investigate the target debt and dividend policies in terms of FOBs and NFOBs. The focus is to analyze how Pakistani firms set their dynamic debt structure along with dividend structure through different institutional environments. The paper identifies the importance of peculiarity of characteristics which shape the dynamic debt and dividend policies in both aforesaid organizational types. The empirical findings of this study provide useful insight into the role of different characteristics associated with FOBs and NFOBs.

3.0 Theoretical Framework



4.0 Methodology

To fulfill the targeted objectives of the study, data ranging from the period 2002-2013 were used. A sample of 280 companies listed at Karachi stock exchange (KSE) was taken. The main sources of data were the annual reports, financial statements and basic balance sheet analyses published by State Bank of Pakistan (SBP). These data pertaining to the values of variables like debt ratio (DR), internal fund (IF), Dividend ratio (DR), net earnings (NE), firm's size (FS), Average account receivables (AR), investments (INV), Tobin q (Q) and return on assets (ROA were taken. Such types of data contained unobservable problems termed as heterogeneity and endogeneity (McVey and Draho, 2005 and Demsetz and Villalonga, 2001). Ownership data such like of this study may have endogeneity problem. Generalized method of moments (GMM) is the best approach to deal with it.

To resolve these problems, panel data methodology and generalized method of moments were applied. Panel data methodology handles the heterogeneity problem while the Generalized Method of Moments (GMM) controls the endogeneity problem.

GMM is just one estimation strategy along with the others. It is a form of Instrumental variable approach which is supposed to be more efficient because it use a richer set of instruments. For instance, dynamic panel models (like the current study) cannot be estimated by OLS, which in those cases is biased. Instead, one should employ GMM. Furthermore, the misspecification of the model was tested by Hansen J-statistic and m_2 statistics. Also, the Wald tests (w_1 and w_2) were used to test the joint significance of reported coefficients and time dummy variables.

4.1 Hypotheses

H_1: FOBs adjust more speedily toward target capital structure than their counterpart NFOBs.
H_2: FOBs rebalance with lower speed toward target dividend policy than their counterpart NFOBs.

4.2 Models Specification

4.2.1 Debt Model

To test the hypothesis-1, in line with (Fama and French, 2002), the model was specified in the following way.

$$DR^*_{it} = a + b\ IF_{it} + cX_{it-1} + E_{it} \text{---------- (a)}$$

The speed is capture by the following model.

$$DR_{it} - DR_{it-1} = d\ (DR^*_{it} - DR_{it-1}) \text{ ---------- (b)}$$

Where $0< d > 1$ is the speed of firms toward target capital structure over time.
By rearranging Eq. (b) we get the Eq. (c) as under:

$$DR_{it} = d\ DR^*_{it} + (1-d)\ DR_{it-1} \text{----------(c)}$$

By putting the value of DR^*_{it} from Eq. (a) in Eq. (c)

$$DR_{it} = d\ a + (1-d)\ DR_{it-1} + bd\ IF_{it} + cd\ X_{it-1} + d\ E_{it} \text{ ---------- (d)}$$

By Putting $da = \alpha_0$, $\beta_o = (1-d)$, $bd = \beta_1$

$$DR_{it} = \alpha_0 + \beta_o\ DR_{it-1} + \beta_1\ IF_{it} + \mu\ X_{it-1} + E_{it} \text{ ---------- (e)}$$

Adjusting dummy variable FOB = 1 for family firms and FOB = 0 for non-family firms, the final shape of the model is as under.

$$\mathbf{DR_{it} = \alpha_0 + \beta_1\ IF_{it} + (\beta_0 + \gamma_1\ FOB)\ DR_{it-1} + \mu\ X_{it-1} + E_{it}} \text{ ---------- (1)}$$

For family firms the impact was captured ($\hat{\beta}_0 + \hat{\gamma}_1$) and for non-family firms ($\hat{\beta}_0$). The speed of adjustment is 1- ($\hat{\beta}_0 + \hat{\gamma}_1$) and 1- $\hat{\beta}_0$ for family firms (FOBs) and for non-family firms (NFOBs) respectively. According to hypothesis-1, it was expected ($\hat{\beta}_0 + \hat{\gamma}_1$) < ($\hat{\beta}_0$

4.2.2 Dividend Model

In order to test the hypothesis H_2, the following model was developed. According to Linter's model of target dividend, the dividend policy was taken as a factor of net earnings of company.

$$DIV^*_{it} = a + b\ NE_{it} + f\ X_{it-1} + E_{it} \text{---------- (f)}$$

It is the fact that firms tend to fill the gap between target dividend ratio and current level of dividend gradually. The speed can be captured by the following model:

$$DIV_{it} - DIV_{it-1} = e\ (DIV^*_{it} - DIV_{it-1}) \text{ ---------- (g)}$$

Where $0< e > 1$ is the speed of firms toward target capital structure over time. By solving the equation (f) and (g)

$$DR_{it} = e\ a + (1-e)\ DIV_{it-1} + eb\ NE_{it} + ef\ X_{it-1} + e\ E_{it} \text{ ---------- (h)}$$

Put $ea = \alpha_0$, $\beta_2 = (1-e)$, $be = \beta_3$ and $de = \mu$

$$DIV_{it} = \alpha_0 + \beta_3\ NE_{it} + \beta_2\ DIV_{it-1} + \mu\ X_{it-1} + E_{it} \text{ ---------- (i)}$$

Adjusting dummy variable FOB = 1 for family firms and FOB = 0 for non-family firms, the final shape of the model is as under:

$$\mathbf{DIV_{it} = \alpha_0 + \beta_3\ NE_{it} + (\beta_2 + \gamma_3\ FOB)\ DIV_{it-1} + \mu\ X_{it-1} + E_{it}} \text{ ---------- (2)}$$

The impact of family firms was captured by ($\beta_2^{\wedge} + \gamma_1^{\wedge}$) and for non-family firms ($\beta_2^{\wedge}$). As proposed in hypothesis-2, it was expected that ($\beta_2^{\wedge} + \gamma_1^{\wedge}$) >$\beta_2^{\wedge}$. The adjustment speed for non-family firms [e = (1-$\beta^{\wedge}_2$)] and for family firms were [e = 1-($\beta^{\wedge}_2 + \gamma^{\wedge}_3$)].

5.0 Descriptive Analysis

In this part of the study, some preliminary econometric analyses were made to find out the difference between mean value FOB and NFOBs identified through threshold level of ownership (25% & 50%), t-statistics was applied. After that some advance econometric analyses were conducted in which the impact of different variables like lag values of debt ratio (DR) and dividend ratio (DIV) along with set of control variables were tested on the current values of DR and DIV for FOBs and NFOBs. Preliminary analyses of debt and dividend ratios along with other firm's characteristics on both threshold levels of ownership (25% & 50%) were given in Table-1. Significant difference was found in both threshold ownership levels. The debt and dividend ratios were found low in family firms as compared to their counterparts. This difference was more prominent on 50% threshold level. It was found that the FOBs had lower size than NFOBs. This lower size provided insight into their operational efficiency over counterparts. Higher level of debt in FOBs strengthened the claim that the creditors prefer them to sanction loans.

The Table-1 shows the basic analysis of means tests between FOBs and NFOBs in their financial characteristics. The sample contains 3360 observations of 280 companies of non-financial sector listed at Karachi Stock Exchange (KSE) Pakistan. The DR_{it} and DIV_{it} stand for debt and dividend ratios of firms respectively. The IF_{it} denotes internal fund. FS_{it} and AR_{it} are the size and average account receivables. AGE_{it} stands for age of firm since incorporated, Q_{it} is the Tobin q and ROA_{it} is the return on assets. The FOBs and NFOBs are classified according the definition as explained in 1. The t-statistic tests are applied to measure the means difference under the null hypothesis. H_0: Mean investment FOB –Mean NFOB = 0. The ***, **, and * indicate significance at the 10%, 5% and 1% level respectively.

Table-1: Descriptive analysis of firm's financial characteristics

	FS_{it}	*9.159*	*9.099*	*9.248*	*-6.183**
	AR_{it}	*0.269*	*0.270*	*0.268*	*9.654**
	AGE_{it}	*3.400*	*3.390*	*3.410*	*0.388*
	Q_{it}	*0.798*	*0.789*	*0.811*	*2.198**
	ROA_{it}	*0.192*	*0.198*	*0.183*	*2.192**

Regarding internal fund, significant difference was found between both organizational types. FOBs had better internal fund than NFOBs. Significant difference was found in both variables i.e. Tobin q and ROA indicated better performance in FOBs comparatively. No significant difference was found in the data regarding account receivables and age of firms on both threshold levels of ownership (25% & 50%).

5.1. GMM Results

This segment of study depicted the results drawn from empirical models using 25% & 50% cut off points for classification of FOBs and NFOBs. The regression results can be seen in Table-2. The estimated coefficients of hypothesis-1 for non-family firms is ($\hat{\beta}_0 = 0.649$) and for family firms were ($\hat{\beta}_0 + \hat{\gamma}_1$) = (0.649 -0.025) = 0.624. Therefore, adjustment speed for family firms was 1-0.624 = 37.6%. For nonfamily firms this speed could be captured as 1-0.649 = 35.10%. This result was significant statistically at 1% level of confidence. The results of hypothesis-2 was supporting our expectation i.e. family firms (FOBs) had stable dividend policy as compared the non-family firms (NFOBs). The estimated coefficients for NFOBs was ($\hat{\beta}_2 = 0.318$) and for family firms ($\hat{\beta}_2 + \hat{\gamma}_3$) = (0.318 + 0.075 = 0.226); showed significant positive impact of previous level of dividend to current level of dividend payment. The speeds of adjustment were computed as (1- β_4 = 1-0.318 = 68.20%), (1-$\beta_4 - \gamma_4$ = 1-0.0.318-0.075 = 60.70%) for NFOBs and FOBs respectively. Thus, the FOBs had lower speed toward target dividend structure or less likely to smooth their dividend policy than NFOBs. It meant that FOBs speed of adjustment lower than their counterparts NFOBs. Our results were in line with previous studies such like (Gugler, K. 2003).The results were also found consistent at higher level of ownership 50% cutoff point.

Table-2 shows comprehensive analysis of dividend and debt policies of family and non-family firms at (25% & 50%) cut off points. Generalized method of moments (GMM) was used to test the hypotheses (1-2). The dummy variable FOB equal 1 for Family business and zero otherwise. DR_{it} and IF_{it} were the debt and Internal fund ratios of the firms. DIV_{it} and NE_{it} are the dividend and net earnings ratios of the firms. $SIZE_{it}$, AR_{it} are the size and average account receivables of the companies. AGE_{it} shows age since incorporated. Q_{it} and ROA_{it} is the Tobin q and return on assets of companies. The sample consists of 3360 observations, 280 non-financial firms listed on Karachi Stock Exchange (KSE) Pakistan for the period ranging from 2002 to 2013. The ***, ** and * denote significance level at 10%, 5% and 1% respectively. T-statistic ($t_{1)}$ shows the linear restriction under the null hypothesis $H_{0:}$ $\beta_0 + \gamma_1 = 0$. T-statistic (t_2) indicates the linear restriction under the null hypothesis $H_{0:}$ $\beta_2 + \gamma_1 = 0$. w_1 shows the Wald Test-1 for the joint significance of the estimated coefficients under null hypothesis H_0 (asymptotically distributed) and the value under parenthesis denotes the degree of freedom. w_2 is the Wald Test-2 for the joint significance of the times dummies under null hypothesis H_0 (asymptotically distributed) and the value under parenthesis shows the degree of freedom. c_1 is the serial correlation Test-1 of order 1 using residual in first difference under assumption of null hypothesis (no serial correlation) asymptotically distributed. c_2 is the serial correlation Test-2 of order II using residual in second difference under assumption of null hypothesis (no serial correlation) asymptotically distributed. h indicates the Hansen test of over identifying restriction under assumption of null hypothesis as no correlation between instruments and error term and the value in parenthesis is the degree of freedom.

6.0 Conclusions and Discussions

The current study was an attempt to examine the impact of ownership structure on dynamic debt and dividend policies, in terms of FOBs and NFOBs. The study was designed to explore the family business models and its effect on targeted financial decisions. Two specific areas were focused regarding both organizational types. First, the dynamics of debt policy with respect to ownership structure was addressed under the shadow of capital structure theories i.e. pecking order and trade-off theories. Second, the dynamics of dividend policy under the umbrella of Lintner's (1956) model of dividend was analyzed.

The results drawn from this study were indicated that the FOBs had higher average adjustment speed (38.70%) toward capital structure than the speed of NFOBs (36.95%). Strong family bond, long term presence of family managers and relations with capital markets made FOBs capable to easier access

toward leverage and rebalance their debt level with higher speed. Similarly, it was revealed that the FOBs had lower rebalancing speed (63.05%) toward target dividend policy. This adjustment speed for NFOBs was captured 71.05%. I was agreed that the FOBs considered more transaction cost as a factor in devising dividend policy (Rozeff, 1982). These empirical evidences provided insight into the behavior regarding corporate performance of FOBs and NFOBs. For example faster speed of adjustment toward target capital structure could have significant positive impact on value. Similarly slower speed toward target dividend policy indicated a positive sign of stability in dividend policy in family owned business (FOB). These results were in line with findings of J. Pindadoa et al. (2012).

7.0 Recommendations

1. It was recommended for NFOBs to take measures against asymmetric information problem.
2. The managers of NFOBs were advised not to let the companies creating a wide gap existing and target capital structures.
3. The investors were instructed to prioritize the future investments in FOBs due to stable dividend policy in them.
4. The Security Exchange Commission of Pakistan (SECP) - regularity authority was requested to monitor the companies regarding stability in their dividend policy especially NFOBs.

Abstract

This paper aims to identify the factors affecting the number of completed, under construction and launched dwellings construction per 1000 inhabitants in Slovakia on the NUTS 3 level in the years 2005-2013 and prepare spatial regression models. Examined characteristics: number of completed, under construction and launched dwellings constructions per 1000 inhabitants, average living area, average monthly wage, unemployment. For comparison of the heterogeneity of individual data were used polarization index (max-min) / average. Pearson's correlation coefficient was used as the degree of dependence of the two indicators. According to the number of sites (n = 8) was also necessary to consider its significance. Moran spatial autocorrelation coefficient (including its significance) was used to measure the degree of spatial autocorrelation of individual indicators. Average dwelling surface showed significant dependence on the average wage only in the years 2009-2011. In contrast, in those years, the number of completed dwellings, dwellings under construction and launched construction of dwellings per 1000 inhabitants is significantly independent on the unemployment rate or the average level of wages. Between years 2005-2008 and 2012-2013 exist between them a direct significant dependence. Linear model exhibits an extreme multicollinearity. It can be assumed that other mechanisms operated during the crisis. Only the average wage does not show spatial autocorrelation. Other characters show positive spatial autocorrelation. Article identifies and analyses the factors affecting the development of the housing sector in the NUTS 3 level in Slovakia. Constructed were classical linear models, spatial lag and spatial error regression models.

Introduction

Housing conditions play a significant role in economic and social prosperity of households. A dwelling or a house connects a household with its surroundings such as public services, shops, friends and family relatives. Last but not least, a housing availability has a huge influence on possibility of employment. Therefore, it is not surprising that housing is relatively expensive and it presents from 20 to 25 % of average income within the EU. Obviously, this share of expenses is for low-incomers much greater than for wealthy people. It is often doubled. If importance of housing will be taken into account, it will not be surprising that from the long-term perspective, majority of European countries supports active housing policy often absorbing from 1 to 4% of gross domestic product (GDP). Some authors were interested in a problem with housing and a social level of inhabitants on various hierarchical levels of the territory. Also, Rasticova et al. (2015) emphasizes that crucial factor in housing will be changes in the population structure, uneven quantitative development of population, aging population and longer life in post-production age (see also Mikusova, Rasticova, 2015). Since 2002, Slovakia is divided into 8 self-governing regions, which are called by the Constitution Higher Territorial Units (see Fig. 1 and Table 1).

The registered unemployment rate in Slovakia in the years from 2002 and 2015 was the most accurately expressed in years 2002 and 2012, when was reported the highest unemployment rate in individual regions. Based on the presented data, it can be stated that in recent years occurred a positive development both in the areas of unemployment, which gradually decreases (Fig. 2), and also in increasing average monthly wage (Table 2) in all regions of Slovakia.

Table 2 Average monthly wage in EUR in the Slovakia by regions in years 2010-2015

Regions of NUTS level 3 are showing disparities, which can be understood in terms of differences in the socio-economic development of regions, resulting mainly in the economic, infrastructural and social disparities in the level of housing, which affects standard of living. Availability and affordability of housing has significant impact on the development and economic performance of the regions.

According to Buckley and Tsenkova (2003), there exist many indicators for assessment of housing construction. It depends on a subject of assessing of the given object of the research or its purpose. There are two basic indicators of housing development of housing construction on a national and local level: a number of completed dwellings per 1000 inhabitants and an average living area of the completed dwellings per capita, Tsenkova writes (2009).

According to Jilek and Moravova (2007), the range of the housing fond cannot be quantified just by a number of dwellings. It is necessary to look at other indicators such as number of living rooms and an overall living area of the dwelling.

Cho et al. (2005) mentions that the housing construction is influenced by many localization factors. A spatial variability of localization factors which are linked directly with housing construction and externalities associated with localization of housing construction. These externalities are called „neighboring influences" because they have an influence on surrounding regions. These externalities are unemployment (Saks, 2008) and migration (Hughes and McCormick, 1981).

A purpose of the article written by Sveda, Krizan (2011) and Spirkova, Ivanicka, Zubkova (2013) is an evaluation of development of housing construction in Slovak cities in the period between 2005 and 2011. They say that a quantitative range of housing construction between 2005 and 2011 is reflection of demand for housing which is the strongest in the cities in Slovakia which provide more working opportunities and which are from a point of economic and social indicators considered as the more developed. Housing construction is an important indicator of an economic and social development of Slovakia regions. Through it, we can observe present processes of transformation of society which is a key element for deepening of regional disparities, Sveda and Krizan say (2011).

A complex viewpoint on a development of a real estate market in Slovakia is written by Spirkova et al. (2013). The authors characterize the factors which influence the development of a real estate market untill the year 2000. They found out that the most significant momentum was the

development of a real estate market after 2000 when its development was influenced by the reforms in housing policy. In doing so, new forms of financing of the housing were introduced which increased a housing accessibility for the inhabitants in Slovakia. Housing should be understood by its attractiveness of cities in a context of increasing their growing potential and a potential of creating working opportunities and so in the context of contributing to realization of Lisbon agenda, according to Vidova (2007).

Methodology

Correlation analysis is one of the most widely used and reported statistical methods in summarizing scientific research data. It is often useful to determine if a relationship exists between two different variables. If so, how significant or how strong is this association between the two variables? The correlation coefficient is a statistic used to measure the degree or strength of this type of relationship (Taylor, 1990). Spatial autocorrelation measures the correlation of a variable with itself through space. Spatial autocorrelation can be positive or negative. Positive spatial autocorrelation occurs when similar values occur near one another. Negative spatial autocorrelation occurs when dissimilar values occur near one another. Moran's coefficient is one of the degrees of spatial autocorrelation. Take values from range <-1, 1>. Its significance was evaluated using Monte Carlo simulation method (Gelfand et al 2010).

Spatial relationships can be modelled in a variety of ways although modelling several forms of spatial relationships at once can lead to problems of identification. A system of spatial lags hypothesizes that the value of the dependent variable observed at a particular location is partially determined by a spatially weighted (or ‘‘neighborhood’’) average of the value of the dependent variable. Such a model cannot be estimated by ordinary least squares because of the problem of simultaneity bias. It must instead be estimated using either IV estimators or ML techniques.

The spatial error model is given by $Y = \alpha + \beta X + e$, where $e = \lambda We + u$ and λ is scalar parameter (Maddison, 2006, p.221).Variability of the characters was evaluated by polarization index IP = (max-min) / average. The greater the value of the polarization index, the higher the variability i.e. polarization of territory is higher according to assessed attribute.

Results and Discussion

In the article are examined the parameters that constitutes the main determinants of the real estate market. We have chosen the following basic parameters: the number of completed dwellings, the number of started dwellings, the number of dwellings under construction, the intensity of the housing, the average floor area of dwellings, the average monthly wage and unemployment. We investigated the links at regional NUTS 3 level in the period 2005 – 2013 in Slovakia. The reason we have chosen these indicators is that they affect both supply and demand for residential property market.

Applying statistical methods we have come to interesting results. The intensity of housing affects the economic situation of the population, which can be observed in the average wage indicator and the unemployment rate. With increasing wage is naturally expected to increase purchasing power and thus acquisition of housing. This fact was confirmed during the period off crisis i.e. until 2009, when the correlation coefficient between the intensity of the housing and the average wage was very low (0.856; 0.88; 0.87; 0.91) and significant (Table 3 – 11).

In 2009, the correlation coefficient decreased significantly to the value 0.552 (p = 0.1234), respectively 0.556 (p = 0.1201) in 2010. In 2011, the value was 0.541 (p = 0.132). After three years, when the correlation coefficient was not only small, but also not significant, in 2012, it again increased to value 0.828 (p = 0.0111) and in 2013 reached value 0.887 (p = 0.0033).

Similarly, when comparing the relationship between the number of started dwellings and average wage, Pearson coefficient between these two characters is also high and significant until year 2010, i.e. it is losing its significance a year later as the relationship between the intensity of the housing construction and the average wage. Pearson's coefficient showed a value close to 0.9, and in 2009 fell to 0.7 (p = 0.0353) and in 2010 was not significant again. The correlation coefficient was 0.577 (p = 0.104) and in 2011 (i.e. a year earlier than the intensity of housing construction) gains significant value again that is achieved also in 2012 and 2013. Relationship quantified using the Pearson correlation coefficient between the finished dwellings and the average wage is high and significant.
It can be expected, and it is natural to expect that the relationship between the unemployment rate and the intensity of housing construction, started dwellings and completed dwellings will be inversely proportional. Calculations have shown that this is true in except the years 2009, 2010, 2011, when the value of the Pearson coefficient in absolute value significantly decreased. In 2012 and 2013, it is again high and significant in absolute value. The jump between years 2011 and 2012 is the most significant according to the number of completed dwellings and degree of unemployment. The correlation coefficient of 2011 is less than -0.162 (p = 0.6763) and it changed to the value of -0.867 (p = 0.0053). From this can be deduced that between the investigated signs and the average monthly wage operate also other techniques we commonly know from the market economy. The same applies to the case of the average dwelling space when in the period off crisis are detrimental rather customs and traditions in determining the dwelling area. Average monthly wage is dominant in the period of crisis i.e. the period of 2009 - 2011. The correlation coefficient reaches the value close to 0.9 (p <0.002) in each year.

Autocorrelation was evaluated using the Moran coefficient. Data of all rated indicators of started, finished and dwellings under construction are in Table 12. In all the evaluated years they show positive spatial autocorrelation. Only one aspect which shows significantly negative autocorrelation is the average floor area of dwellings in 2005. Due to the spatial character and extreme multicollinearity of linear regression models, we started modelling spatial relationships using regression models.

Source: own processing

For the number of dwellings under construction per 1000 inhabitants is spatial error model suitable for all evaluated years. The average wage, unemployment rate and lag coefficient lambda are statistically significant throughout the whole period of 2005-2013.

Signs of the coefficients are in line with expectations - positive for the average wage and negative for unemployment rate. The regression coefficient for unemployment is much higher.
The coefficient R2 is greater than 0.9 except in 2013, when the value reaches 0,876 (Table 13a-13c).

Analogous conclusions apply also on other examined indicators. For the number of **completed dwellings** per 1000 inhabitants, spatial error model is suitable for all the evaluated years except the years 2009, 2012, 2013.For 2009 and 2013 is spatial error suitable only as an independent variable of average wage. The average salary is statistically significant throughout the period 2005-2013.
Signs of the coefficients are in line with expectations - positive for the average wage and negative for unemployment rate. The regression coefficient for unemployment is much higher. The coefficient R2 is close to the value of 0.9; has never decreased below 0.8.

For the number of **started dwelling**s per 1000 inhabitants is spatial error model suitable for all the years evaluated except the years 2008, 2011, 2012, 2013. For the years 2008, 2012, 2013 is suitable spatial error model with independent variable - the average wage. The average wage, unemployment rate and lag coefficient lambda are statistically significant throughout the whole period of 2005-2013.
Signs of the coefficients are in line with expectations - positive for the average wage and negative for unemployment rate. The regression coefficient for unemployment is much higher. The coefficient R2 has not dropped below 0.80 at any model.

Conclusion

The objects of review were indicators: number of completed dwellings, the number of started apartments, the number of dwellings under construction, the average floor area of dwellings, the average monthly wage and unemployment. We consider those indicators as determining, as they have a major impact on supply and demand in the residential property market. With the application of mathematical and statistical methods we reached the results that show the nonstandard behavior, respectively connections between the indicators examined in the crisis, i.e. between 2009, 2010, 2011.Living and social status of the population is actually in the strong binding. It seems necessary to address social problems in symbiosis with economic and environmental contexts. Housing is the best example of that. The importance of housing in a long run highlights that most of the European countries support housing policy and contribute a certain percentage from GDP usually from 1 to 4 percent.

Housing is an important source of employment. This applies to a wide range of services related directly or indirectly to housing. Services for households and the services provided within the community related to the urban environment are a significant source of employment and are often organized and provided also with services directly related to housing.
What challenges XXI. Century means for housing?

- Increased mobility between regions,
- population migration to centers of urban character,
- changes in household structure - from the nuclear family to the free-form households, reduction of household members,
- lifestyle changes - smaller families, fewer social communication at work, call for deeper and more extensive communication within the free time activities,
- changes in health care - greater part of health care activities at home,
- changes in value systems in favor of the health aspects of the environment,
- reduction of the time devoted to the work,
- work at home,
- increased cost of living and the limitation of resources,

- workforce flexibility.

Housing will change in the context of new technical and technological changes affecting the technology of environmental protection, construction technology, management and efficient use of energy and water, security of buildings, technology of implementation of functions in the living space such as preparing meals, access to information, communication and education.

Abstract

The main objective of the study is to investigate the impact of Merger & Acquisition (M & A) on financial performance of the firms. Twenty six transactions of M & A happened in Pakistan ranging from the period of 1999-2011 were analyzed. Five main financial variables like liquidity ratio, activity ratio, leverage ratio, interest coverage ratio and the profitability ratio were applied to gauge the financial performance of the firms. Sophisticated techniques like Data Envelopment Analysis (DEA) and differential tests were applied to estimate the results. The empirical results showed that the performance of post-mergers were better than pre-merger in both financial and non-financial sectors. Furthermore, it was found that the performances of financial sectors were comparatively better than non-financial sector. The merger and acquision's activity was recommended strongly in financial sector. Moreover, in non-financial sector merger and acquisition was suggested under the observations of regularity authority.

Key words: Merger & Acquisition; Financial performance; Financial and non-financial sector

1.0 Introduction

Merger is defined as when two organizations decide to share common interest and ownership as a single entity or together to achieve their shared benefits, and to gain competitive advantage over other competing firms. Acquisition is well-defined as when organization procurements some assets, plant & equipment, strategic business units, or shares of the other company (Sudarsanam, 2003). Organizations use merger and acquisition (M & A) to achieve its various objectives to compete in the global business environment such as growth. An organization has the right to choose the type of growth strategy which is best suitable according to its business and competitive milieu (Ashfaq, 2014).

Three times escalation has been comprehended in the growth of the M & A activity in the US only in the 20th century and five times increment can also be seen in the total value of the activities. The UK along with other developed nations has also followed the same pace of development in the M & A activity (Afza & Yusuf, 2012). Most of the deals of M & A have taken place in last decade in China, Indonesia, Singapore, and Taiwan. The expansion in the activity is due to the unperturbed polices for the foreign investors and they found greater opportunities in these regions to come and acquire or merge the firms.

In Pakistan, M & A process is not fully grown in relation to the other developed countries because of the involvement of the Pakistani Government, nationalization of the institution in 1970s which decreased the rate of growth mainly in corporate and private sector of the economy. (Abbas et al., 2014) and there is a considerable research gap present in Pakistan when we compare them with the numerous studies conducted in the other developed countries because this activity has been fully grown in the advanced economies (Aamir, Kouser & Chaudhary, 2014: Bashir, Sajid & Sheikh, 2011).

The following figure shows the M & A activity in Pakistan from 1995 to 2015 both in terms of no. of deals & value and is taken the from the institute of Mergers & Acquisitions and Alliances (IMAA) analysis. In Pakistan, detail information about the firms who engaged in M & A activity is taken from the website of Karachi Stock Exchange and from the Competition Commission of Pakistan. According to the website of KSE, total number of deals held from 1995-2015, are 126. The Competition Commission of Pakistan stated that total numbers of merger events held are 51 and the 208 acquisitions are held. According to the sample size of the current study from 1999-2011 the number of events held in Pakistan are 107 as per the list available at the Karachi Stock Exchange website. A greater no. of events has been taken place in the financial sector of Pakistan.

In this current study the financial and non-financial sectors of the Pakistan are taken to investigate the pre and post-merger & acquisition performance from the 1999 to 2011. In financial sector, most prominently banks are involved in the economy and this study has selected the merger and acquisition deals of the banking sector from 1999 to 2011. On the other side, for the comparative analysis of the both sectors, financial and non-financial, this study has employed the textile, cement and pharmaceutical firms under the head of non-financial sector merger and acquisition deals from 1999 to 2011.

A list of various studies conducted in Pakistan about M &A activity has been presented in the literature review chapter which gives detail outlook about the M & A studies held in Pakistan. The current study finds the scope of the comparative analysis of the financial and non-financial sector merger and acquisition events held in Pakistan.

1.1 Objectives of the study:

- To differentiate the impact of M & A of financial sector of Pakistan
- To differentiate the impact of M & A of non-financial sector of Pakistan
- To test the operational efficiency of the pre and post-merged or acquired firms
- To measure the risk of the pre and post- merged or acquired firms
- To quantify the profitability of the pre and post-merged and acquired firms
- To give recommendations for the policymakers

1.2 Significance of the study:

Few studies have been conducted to evaluate the financial performance of non-financial sector of Pakistan before and after M & A deals. This research study will contribute to the concerned companies, managerial implications and to the policy makers by comparing the pre and post financial performance of M & A events held in financial and non- financial sector from the time period 1999-2011.

2.0 Literature Review

Now a days' business rivalry is changing the scope of business and borders of terrestrial regions because in this rapidly varying business environment organizations adopt the various procedures and strategies. M & A is one of the various growth strategies used by the organizations to compete in the rapidly changing environment (Kouser & Saba 2011). Trautwein (1990) and cox (2006) both have stated that there are numerous reasons due to which firms involve in the activity of M & A. They have mentioned the various objectives and motives under the head of various theories in an organized and logical way.

Selcuk, E. & Yilmaz, A. (2011) assessed the financial performance of selected 62 companies with the help of accounting data. The financial performance of banks in Indonesia was improved after merger & acquisition activity. Same trend has been seen in studies conducted in Europe and US. Banking sector of both countries showed the improvement in the post-merger financial performance respectively by Altunbas & Marques, 2008; Housten et al., 2001). The improvement has been shown after the M & A deals in the manufacturing sector of India. Beena (2004) analyzed the post-performance of firms by using the various indicators of financial performance with the help of t-test.

Rahman & Ayorinde (2013) studied the post-merger performance of the banks in the Nigeria. They scrutinized with the purpose to find effect on the performance of the banks after the M & A. Bank performance was measured with the help of ROA (return on assets), ROE (return on equity) and net profit margin. On the other hand, independent variable namely merger was also measured in terms of the following (strategic decisions), operating competence, asset profile, liquidity menace, capital configuration, and credit risk. Data were tested with the multiple regressions. The study showed that there is a positive relationship between the strategic decisions of mergers and the bank performance. The strategic decisions strappingly influenced the performance of banks. The research concluded that mergers can be used as a strategic tool to enhance the performance of the banks as well as mentioned that banking management must accept and apply the various strategies on products to enhance the revenues of the banks (Rahman et al., 2013). Another research on the corporate sector performance before and after merger had been carried out in India by Kumar & Bansal (2008). The study summarized the result that most deals gained the competitive benefits, increased efficiency, and the improvement in cost of business. The post-merger performance of the Indian corporate sector was improved over time.

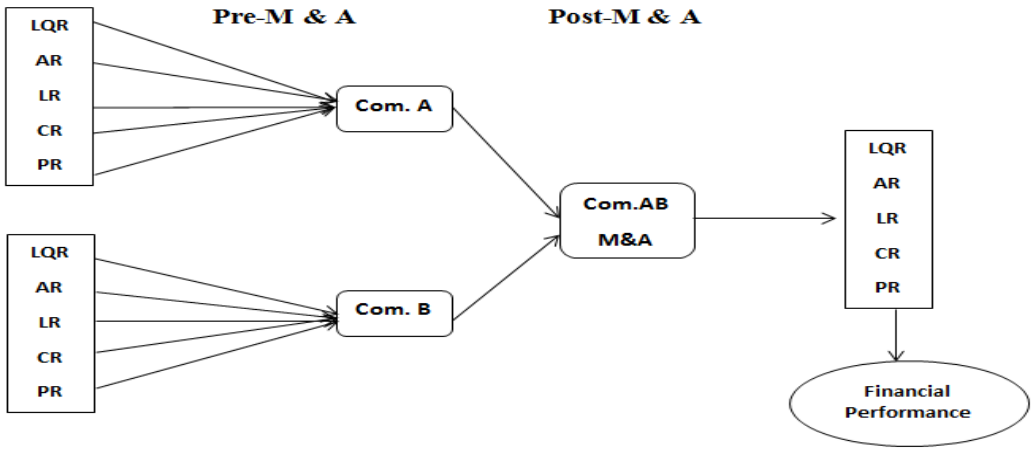
Usman, Khan, Wajid & Malik (2008) studied the impact of M & A deals of textile sector in Pakistan in terms of their operating and financial performance occurred during 2001-2005. The final results of the study demonstrated that pre-merger financial performance was better of the textile firms in Pakistan when compared to the after merger performance of firms. Fatima & Shehzad, (2014) conducted a research study to test the influence of M & A on the profitability of banks after merger deals. Sample size for this study is ten banks that were undergone into the process of merger and acquisition from 2007-2010. Data were gathered from the annual reports of the banks and to made comparison of their financial performance three years before M & A and three years after M & A data were collected. The study reveals that this practice has no optimistic effect on the banks fiscal health. The SPSS test, paired sample t-test shows that there is no significant impact of M&A on the banks financial performance except the return on equity (ROE).

In this paper, the profitability of the Royal Bank of Scotland (RBS) after merger has been investigated with the help of accounting and financial ratios in Pakistan by Kemal (2011). Data were taken from the year 2006-2009 and most frequently used 20 financial ratios were employed in the study to analyze the financial performance of the bank post-merger. The study clearly depicted that all the financial ratios employed in the study has positive relationship with the performance of the bank before the merger; this showed that there is no confident effect on the enactment of RBS after merger.

Another study concluded that efficiency and the size of bank are positively related with each other (Mehmood & Loan, 2006). The study further stated that foreign banks in Pakistan are more efficient

than the private banks from the time period 1994 to 2000.They used the SFA technique to calculate the performance of banks who involved in the activity of M & A. Merger and Acquisition has become mostly widely used strategy by the organizations to meet challenges of the vibrant business milieu (Abbas, Hunjra, Saeed, Hassan & Ijaz 2014). This paper examines the financial performance of banks in Pakistan that involved in the M & A activity. Data were gathered from the yearly reports of the banks taken from the State Bank of Pakistan. Sample size for this study is 10 banks and the various 15 financial proportions are employed to measure the pre & post fiscal performance of the banks. In this paper, paired sample t-test was also employed to gauge the pre and post difference in performance of banks. The result depicts there is no noteworthy difference in the enactment of banks in Pakistan before and after the M & A (Abbas et al., 2014).

2.1 Theoretical framework:



LQR= Liquidity ratio, (current ratio, quick ratio)
AR= Activity ratio, (sales growth ratio, total asset turnover ratio)
LR= Leverage ratio, (debt to total asset ratio, debt to equity ratio)
CR= Coverage ratio, (interest coverage ratio)
PR= Profitability ratio (return on asset, return on equity, net profit margin & earnings per share)

3.0 Methodology of the study

3.1 Interest variables of study

This research is a comparative study which scrutinizes the impact of M & A on financial performance of all merged firms in Pakistan from 1999- 2011 from financial and non- financial sectors of Pakistan. So this study is mainly based on the independent / exploratory variable, M & A events and the dependent variables are the eleven financial ratios. Current ratio, quick ratio, asset turnover, sales growth, debt to total asset ratio, debt to equity ratio, interest coverage ratio, return on asset, return on equity, net profit margin and the earnings per share.

3.2 Sample size of study

In financial sector mainly banking merger & acquisition deals have been taken and in the non-financial sector textile, pharmaceutical and cement sectors' deals have been included. Total 26 deals were selected from time period 1999-2011 in both sectors. In non-financial sector 15 and in financial sector 11 deals were observed during the specific time period. The study put forward hypotheses and tests them through statistical data analysis technique and the Data Envelopment Analysis. Sample

size of the study was selected on the basis of simple random sampling technique. A list with complete information of M & A activity in Pakistan is given below in the Appendix.

3.3 Data Collection

Data were gathered three years for both the acquiring and target companies to evaluate their pre and post- merger financial performance. The logic behind selecting the data 3 years for pre-merger and three year for pot-merger performance is that Yener & David (2008) and Abbas et at., (2014) stated that longer time period can deteriorate the financial performance of the firms particularly from the view point of post-merger performance because the other external factors & variables can negatively affect their financial health.

Data has been collected from the SBP's published financial statement analysis for the non-financial companies of Pakistan and some annual reports were collected form the library of SBP in the hard form from Karachi. The data collected for the research study is cross sectional because it has been collected at one point in time and the unit of analysis is individual organization.

3.2 Hypotheses

H_1: There is a positive relation after the merger & acquisition on firms' financial performance in financial sector
H_2: There is confident association after the merger & acquisition on firms' financial performance in non- financial sector
H_3: There is an optimistic impact on the operational efficiency of the firms after the merger & acquisition
H_4: There is a positive effect on the risk position of the firms after the merger & acquisition.
H_5: There is a confident link on the performance of the firms after the merger & acquisition.

3.4 Statistical method

The current study is analyzed with the help of two different techniques; namely paired sample t-test which is used for the differential studies and other is Data Envelopment Analysis (DEA). This study is a differential research in which the two companies are compared by their performance, pre and post-performance. For each company three years pre and three years post data has been collected and then compared (set wise). Ahmed & Ahmed (2014) stated that financial ratio analysis is used to gauge the performance of two effects. They further stated that this method of measuring performance is appropriate and best proxies can be employed for the ratio analysis. The current study uses the various eleven ratios to measure the financial performance expending the paired sample t-test. In the second part, Data Envelopment Analysis technique is used to measure the relative performance of the financial and non-financial sectors of Pakistan in terms of productivity and technical efficiency. DEA is an efficiency model and a non-parametric technique. Farell & M.J (1957) stated that, 'DEA is a mathematical programming technique. Two different approaches, production and intermediation can be used to measure the efficacy by DEA. This research study has taken the intermediation approach which is further categorized into input oriented analysis and the output oriented analysis by taking the conjecture of CRS (constant return scale) and the VRS (variable return scale). The online software of DEA is used to gauge the financial performance of the firms from both sectors.

4.0 Empirical Results

Table 4.1 and 4.2 shows the summarized ratio analysis for the financial and non-financial sector respectively and are given below in appendix. Comprehensively, the fallouts of financial ratio analysis for the banking sector from 1999-2011 reveal the declining results for the following ratios, current ratio, debt to equity ratio, interest coverage ratio, & return on asset ratio. Current proportion, debt-to-equity fraction and asset turnover ratio insignificantly decline, whereas the interest coverage

ratio significantly declines; which means that firms have weakened their abilities to meet the interest expenditures after the M & A. See results below in table 4.1. While quick ratio, asset turnover ratio and debt-to-total-asset ratio insignificantly improves after the M & A. Return on equity and earnings per share significantly improves after the events taken place. These two ratios shows the significant improvement in performance after the event while on the other hand sales growth ratio insignificantly remain the unchanged and the net profit margin ratio significantly remain same in post-period.

The comprehensive analysis of the paired sample t-test shows the insignificant performance of non-financial sector firms after the M & A event for the following ratios; current ratio, quick ratio, debt-to-equity ratio, debt-to-total-asset ratio, return on asset ratio, and earnings per share ratio. The current and quick ratio indicates that after the event firms insignificantly improve their liquidity position. While the asset turnover ratio depicts significant improvement and sales growth significantly decreases. Debt-to-equity ratio & debt-to-total asset ratio shows the momentous impact before the events while these ratios becomes insignificant after the event and depicts the increasing trend; which means that non-financial sector overall improved their solvency position. Interest coverage ratio significantly decreases showing that non-financial sector weaken its abilities to pay off its interest expenses in post-period performance. Profitability of these firms decreases after the merger & acquisition event. See table 4.2.

4.1 Comparative analysis

The comparative analysis of the both sectors is offered above in table, 4.3.The fallouts specify the performance of both sectors in the form of ratios. The financial sector, aggregately improves its financial performance in the following ratios namely, ATO, IC, DE and the EPS. While all other remaining ratios, CR, QR, SG, DA, ROA, ROE and NPM shown the declining trend overall. On the other hand, non-financial sector in aggregate analysis has shown the improvement for two ratios after the merger and acquisition, DE and the DA which means that solvency risk position improved for the firms and the total assets are performing efficiently to generate profits for the business.

The comprehensive and comparative analysis of the both sectors of the economy is presented in the table 4.3. The comparative analysis of the both sectors shows that the financial sector has shown the improvement in the four ratios while the non-financial sector did not perform well in comparison to the financial sector for all the events from 1999-2011. The financial sector after the merger or acquisition performed better in comparison to the non-financial firms; the reason behind is that banks are under the protection of the SBP and it maintains strict check and balance on them which makes their performance better.

The table 4.4 presents the results of the DEA applied on the eleven sample banks. The table shows the efficacy of the banks after the M & A by using the constant return to scale method. The study concludes that on average the banks perform efficiently in the post period. On the other hand, the non-financial sector on aggregate shows the inefficient performance after the M & A. See table 4.4 and 4.5 below in appendix.

5.0 Conclusion and Recommendations

The economy of the Pakistan is in very fragile condition and facing the numerous challenges nationally and internationally. The Merger & Acquisition is the strategy and most widely used tool all over the world to compete with the rapidly changing business ambience. It is the obvious restructuring tool to the businesses of the Pakistan to compete and take competitive edge to the competitors and to gain strong footings in the industry nationally and internationally. In Pakistan, the research has not been conducted widely and on larger scale as compared to the internationally conducted studies on this topic. However, this study has filled the gap in the literature review in measuring the financial performance of banks and non-financial firms from the textile, cement, and pharmaceutical industries from the time period of 1999-2011 by collecting the three year pre and three year post data for all the firms involved in the activity from their annual reports.

According to the results of the study, it can be safely described that the financial sector of the Pakistan has shown better performance as compared to the non-financial sector of the Pakistan after the mergers and acquisitions deals. It means that banks performed well after the event taken place measured in terms of financial ratios than the non- financial firms. However the overall results for both sectors are not proved significantly positive which means that comprehensively this growth strategy has not performed well for the development of the corporate sector and the economy overall in Pakistan.

The current study also formulates the suggestions and recommendations to the policy makers that they must formulate and design a comprehensive mechanism through which companies should take suitable steps before being involve in this activity.

1. The companies and the banks must have resources to fairly gauge the financial performance of the engaged companies before the event and have an estimated performance report after the event, i.e. post financial performance after the M & A.
2. The objectives and advantages of the M & A may not be ignored by the companies to achieve and have to develop and maintain cost synergies and so on.
3. The responsible institutions and the policy making bodies must have to develop the mechanisms that may upsurge the events of the M & A in the country in various sectors of the economy and to make them successful in terms of their financial performance which will be ultimately beneficial for the economic growth and development of the Pakistan.

Abstract

The scenario in Malaysia, charitable organizations is challenged to raise significant donation to cover high demand for their services. For charities to survive in competition, they have to depend more on individual donors and less on the government for funding in order to survive. While the topic of charitable giving has been substantially studied, no known research has explored the applicability of the theory of planned behavior (TPB) in the context of individual charitable giving intentions and behavior. In addressing the research gap, this paper details a preliminary study which examined the influence of attitude, subjective norm, and perceived behavioral control and another two extended variable which is religious belief and trust on charitable giving intentions and behavior. Data were obtained via a survey on 347 individual donors in Kuala Lumpur, Malaysia. The results of the PLS analysis indicated that attitude, perceived behavioural control, religious belief and trust significantly predicted individual intention to undertake charitable giving. Contrary to expectations, the data did not provide support for the influence of subjective norm toward individual decisions to undertake charitable giving. This study will make the upper management of the non-profit organizations to understand about the different indicators that can affect charitable giving and will help to find out the characteristic that have positive impact on donations as well as on individuals. Thus, this study will be useful for all non-profit organizations to understand and influence donors/individual to donate in their organizations.

Keywords: Charitable Giving, Individual Donor, Partial Least Square (PLS), Theory of Planned Behavior.

1.0 Introduction

Charitable giving can be defined as the act of giving money or other items of value to charitable organizations without expecting anything in return (Oxford Dictionaries, 2014). Charitable giving commonly takes in a form of cash, and can also be real estate, motor vehicles, appreciated securities, clothing and other assets or services. Charitable giving is one of the approaches that can reduce the wealth gap in societies. The public donations are helpful to support the needy people in an era where government funding has been limited. In order to generate public funding, organisations need to understand the intentions and behavior of donors (Eng Ling,2012). However, the efforts to study the donor behavior and specifically intentions to donate money have not been studied extensively (Knowles et al., 2012). Understanding the motivation and intentions to donate money is important to develop effective marketing strategies which can generate charity from individuals to fund

emergencies and disasters. Charity organisations are struggling hard to raise funds to help the underprivileged. Over the years, the public donations are inconsistent with an overall declining trend towards charity donations (Eng Ling, 2012). On the other side, need to raise funds is rising rapidly and if this problem will not be tackled, it can cause trouble for the poor and needy (Sargeant et al., 2002). Some studies has been conducted in a developing country context but so far identified the role of demographics to explain the predictors of charity donations (Lord, 1981; Burgoyne et al.,2005;Lee and Chang,2007).These studies highlighted the gender and age differences to explain charity intentions but could not figure out as why people make donations (Smith and McSweeney,2007). Despite the significance of this issue, the author did not find clear studies in Malaysia to help better understand factors that motivate individuals' donor to undertake charitable giving in Malaysia. In fact, it was surprising to find that Theory of Planned Behavior (Ajzen, 1985) which is broadly utilized intention-behavior model has not been actively applied into area of charitable donation (Bartolini, 2005). Although Theory of Planned Behavior has received substantial empirical support with strong predictive utility, many studies have already attempted to extend and enrich the model by including additional explanatory variables.

Thus, this study are intended to proposed a framework by looking at the case of individual donors in Malaysia to develop a better understanding of Malaysian donor's by using the components from the Theory of Planned Behavior and another two additional variables which is religious belief and trust. Next the paper presents previous literature on the components and an overview of the methodology and the proposed framework for the current study.

2.0 Theory of Planned Behavior

The theory of planned behaviour (TPB) was developed by Ajzen (1985). Theory of Planned Behavior (TPB) is an extension of TRA with perceived behavioral control added as a variable for predicting intentions and behavior. Perceived behavioural control is the extent which a person feels able to enact the behavior. Intentions to perform behaviors of different kinds can be predicted with high accuracy from attitudes toward the behavior, subjective norms, and perceived behavioral control; and these intentions, together with perceptions of behavioural control, account for considerable variance in actual behavior. The combination of strong empirical support and widespread applicability has contributed to the popularity of the TPB. The TPB has been applied to the study of entrepreneurial intent in 12 countries representing all ten of the global region clusters as identified in the GLOBE project(Engle et al., 2010), the intention to use internet stock trading among investors in Malaysia (Gopi & Ramayah, 2007), Individuals' volunteer intention for future sporting events (Bang, A. Odio, & Reio, 2014), to predict Danish adolescents behavioural intention for healthy eating (Grønhøj, Bech-Larsen, Chan, & Tsang, 2012), and internet purchasing behavior (George F. Joey, 2004). There has been little research on charitable donation and charitable giving using the TPB. There are three components in TPB:

(i) Attitude toward charitable giving

The first construct of TPB is attitude where it is defined as an overall evaluation of one's behavior. Attitudes as an important psychological constructs have been found to influence and predict many behaviours. The TPB defines attitude toward behaviour as "the degree to which a person has a favourable or unfavourable evaluation or appraisal of the behaviour in question" (Netemeyer, Ryn, & Ajzen, 1991). According to Linden (2011), the attitudes to donate are measured using favourable indicators, similar to what is produced by the researcher conducted by Smith and McSweeney (2007), which also predict a person's intention to make donation. According to Cheng et al. (2006), before deciding to engage in a certain behavior, a person tends to assess the benefits and costs resulting from the behavior. So, when a person has positive attitude towards a specific behavior, she is likely to perform the behavior in question (Ajzen, 1991,2006;Cheng et al.,2006; Han et al., 2010). Regarding the attitudes to make charitable giving, the researcher measured this variables by asking questions regarding the pleasant, useful, favourable, good and important in making donations.

(ii) Subjective norms

The second determinant of behavioural intention is subjective norm which represents the beliefs about the normative norm of significant others (Ajzen, 2002). Subjective norms can be defined as "the perceived social pressure to perform or not to perform the behaviour" by the individual (Netemeyer, Ryn, & Ajzen, 1991). Theory of Planned Behavior explained subjective norm as a construct the determined by normative belief which is the expectation that comply with motivation that an individual in common, where a person like to perform something that other person such as their family members, friends, supervisor or the society like to perform since they perceived the behavior is appropriate to perform. This is where, a person will be using information about others in order to adjust their own behavior and as a result, he or she will perform the same behavior and perceived it as a common behavior in the group. According to Bidin et al. (2009), the subjective norm is associated with the belief that is conveyed by others, both by individuals and through the response of a group. The subjective norm can be understood as a reaction for someone to do something because of the pressure from others or a belief that becomes important when he does it to measure this variable of subjective norm, some questions items relating to other people support will be important, desirable, and whether or not someone is doing a particular activity.

(iii) Perceived behavioural control

The third independent variable of intention is perceived behavioural control. It seen as the perceived ease or difficulty in performing a behavior (Ajzen, 1991). Netemeyer, Ryn, & Ajzen, (1991) described perceived behavioural control as: "the perceived ease or difficulty of performing the behaviour". In addition, perceived behavioural control "is assumed to reflect past experience as well as anticipated impediments and consequences". PBC is basically an individual perception of their ability to perform a behavior. It is based on the individual feeling of having control over their own behavior. Usually, PBC will tend to exist when a person estimate the level of difficulty for him or her to perform a specific behavior. This is where the an individual control belief will influence his or her actual behavior Specifically, perceived behavioural control assesses 'the perception of how well one can control factors that may facilitate/constrain the actions needed to deal with a specific situation' (Han et al., 2010). Linden (2011) concluded that behavioural control can only occur in a particular action. Another action is one that occurs as it is influenced by factors beyond control. He posited that the driving behavior is delayed by the engine problems. Several factors come into consideration to form the PBC's variables which are the ability, willingness, and control to make charitable giving.

Based on the TPB factors the following hypotheses are depicted:

H1: Attitude has significant effect on charitable giving.
H2: Subjective Norm has significant effect on charitable giving.
H3: Perceive Behavioral Control has significant effect on charitable giving.

2.1 Extended Theory of Planned Behavior

Even though the theory of planned behavior has received substantial empirical support with strong predictive utility (Ajzen and Drive, 1991a; Conner,Warren, and Close, 1999), many studies have already attempted to extend and enrich the model by including additional explanatory variables (Broonen, 2001; Conner and Araham, 2001). Even Ajzen (1991) who introduced the theory proposed that the TPB is open to the inclusion of predictions, "if it can be shown that they capture a significant proportion of the variance in intention or behavior after the theory's current variables have been taken into account". These external variables indicate any independent variables that are not included in the theory. Demographic variables (e.g., age, gender, occupations, education, and religion), attitude toward target, and personality traits are some of the external variables mentioned in the theory (Ajzen and Fishbein, 1980). The primary concern with these external variables is that even though they may be related to the behavior in question, they do not directly influence behavior (Ajzen and Fishbein, 1980). For the current study, there are two additional variables which is religious and trust:

(i) Religious

Religion has been acknowledged by researcher as an important influence of human behavior (Lau and Tan, 2009) this is due to it is the most universal and influential social institution that give a greatest significant influence towards human attitudes, values, and behaviour (Alam, Mohd, & Hisham, 2011). According to Kasri (2011), he stated that in his study the strongest motivator for charitable donations is religion. This is due to people or individual especially a Muslim tend to make charitable giving because of the responsibility towards the society. The most powerful driver of religious giving motivations is receiving a return on charity in the afterlife (Skarmeas & Shabbir, 2011).

Schlegelmilch et al. (1997) clearly highlighted that 'donating' is a fundamental religious teaching and thus it is a key consideration when evaluating the influence of religiosity on donation behavior. Some of the past studies have shown that there is a direct impact between religiosity and attitude towards helping others and attitude towards the charity (Ranganathan and Henley 2008). Studies have also found that religious involvement will have positive influence on various forms of civic behaviour and charitable giving (Perks and Haan, 2010; Jackson et al., 1995). However, others have rejected these findings and found that there are no significant relationships between religiosity and charitable donation in an Australian context (Kanabar, 2004). The findings suggest that there must be more to religious belief than a direct impact on charitable donations. Based on religious teachings and it is predicted that it could have moderating effect in a charitable donation context. That is, if an individual is bounded by strong religious beliefs, they will value the charity's work even more. As the result, it will increase the likelihood of the donation.

(ii) Trust

Charity organizations strongly depend on the public's trust. Donors often do not know what happens exactly to their donations, how much is saved for overhead costs, and where the money is actually spent. This lack of transparency is dangerous because an occasional media report of poor performance and misallocation of funds may easily scandalize the entire philanthropic sector (Bekkers, 2003).

According to Sargeant and Lee (2004), public trust refers to the extent of donor belief that a charity will behave as expected and fulfil its obligations. Public trust is essential to the success of charitable organizations. It not only provides resources for charities, strengthening commitment of the public, but also offers charities a higher moral tone than other sectors (Sargeant and Lee, 2004). The failure to maintain public trust could lead to negative consequences, including decreased donations, image damage, diminished autonomy, or even organizational collapse. Thus public trust provides a premise for charities to perform. On the other hand, public trust is largely gained from good performance of the third sector, because people public trust charitable organizations mainly based on their good experiences with them and the belief that they are able to perform well (Luhmann, 1979).Thus the level of public trust in a charity might be able to indicate how well or how badly it performed. And the result of public trust assessment would be helpful for detecting the way to improve charity performance and secure the source of support from the general public.

Based on the extended factors the following hypotheses are depicted:

H4: Religious Belief has significant effect on charitable giving.
H5: Trust has significant effect on charitable giving.

3.0 Methodology

Respondents

The unit analysis was individual donor who had donated in the last one month. Based on the model of Structured Equation Model (SEM) complexity and basic measurement model characteristic, the minimum sample size required for this study is 100- 150 sample (Hair et al.,2010;Knowles, Hyde

and White (2012). In this study, there were 350 people approached in the city of Kuala Lumpur by the researcher.

Table 1: Profile of respondents

Demographic	Scale	Percentage (%)	Scale	Percentage (%)
Gender	Male	42.7	Female	57.3
Age	<20	7	41-60	26.4
	21-40	64.5	>61	2.1
Marital Status	Single	34	Divorced	0.6
	Engaged	5.8	Widowed	0.3
	Married	59.4		
Individual income per month (MYR)	< 1000	7.7	<2000	25.7
	<3000	26	<4000	13.3
	>4001	12.7		
Level of education	PMR/SRP/LCE	6	SPM/STPM	30.8
	Certificate	5.2	Diploma	21.9
	Above Degree	40.9	Other	0.6
Number of persons in household	<2	16.1	3-5	64.6
	>6	19.3		

Table 1 outlines the demographic profiles of respondents whom participated in the study. There were more females (57.3 per cent) than males respondents (42.7 per cent). In terms of age, the majority of the respondents fall between the "21-40 years of age" (64.5per cent). In addition, the majority of the respondents are "Married" (59.4 per cent) or "Single" (34 per cent). Further, a large group of respondents recorded an income fall into "less than RM3, 000 income" (26 per cent). A majority of the respondent "Degree and above" (40.9 per cent) or "SPM/STPM" (30.8 per cent). Moreover, most respondents have "3-5 numbers of people in household" (64.6 per cent).

Measurement

This study is a quantitative research study. We used a survey questionnaire to collect data. The questionnaire used was adopted form Kashif & De Run (2015), Teah, Lwin, & Cheah (2014), and Australian Charities and Not-for-profits Commission (ACNC) survey (2013). The questionnaire comprises seven sections of which one section is on demographic information and the remaining six have five-likert-scaled items measuring attitudes, subjective norm, perceived behavioural control, religious belief and trust.

Data Collection

In order to collect data, a few shopping malls located in the city of Kuala Lumpur were chosen as per convenience. There are many young people from surrounding small town who travel to the city for the purpose of work, study, and their personal business. The respondents were qualified through a screening question (i.e. have you donated money in the last one month?) The core objective behind this qualification of respondents was to gain insights from those who have actually donated. Once the initial qualification of respondents was completed, the researcher sought approval from individual respondents to participate in the study on a voluntary basis. There were 350 questionnaires distributed among the potential respondents, and 347 were found fir for data analysis.

4.0 PLS data analysis and results

The research model was evaluated using PLS which is a variance-based approach to structural equation modelling (SEM) (Hair et al., 2014). Three aspects of PLS render it a fitting statistical tool for this study. First, PLS is well suited for analysing predictive models with multiple-item construct.

Second, if appropriately applied, this method offers high efficiency in parameter estimation which manifiested in its greater statistical power than that of covariance-based SEM (Hair et al., 2014). It can also simultaneously test the measurement model and the structural model.

Stage 1: The measurement model

Assessment of the measurement model subscribes to a number of criteria. First, we assessed the convergent validity of the scales by applying three indicators namely factor loadings, average variance extracted (AVE), and composite reliability. As reported in Table 2, the factor loadings for all items exceeded the recommended value of 0.6 (Lee and Kozar, 2008) indicating convergent validity.

Table 2: Factor loadings and cross-loadings

Besides factor loadings, AVE, composite reliability, and Cronbach's Alpha value for all the constructs were also examined. Table 3 shows that all AVE values exceed the recommended value of 0.5 (Fornell and Larcker,1981), suggesting adequate convergent validity. Similarly, the composite reliability values were well above the recommended value of 0.70 (Hair et al., 2010). Also the Cronbach Alpha values met the minimum threshold of 0.60 (Hair et al., 2010). Acceptable or high internal consistency demonstrates that appropriateness of the scale used in capturing the construct under investigation. On the basis of the overall results, we can conclude that the items used in this study have acceptable convergent validity. Hence, all items were retained for further data analysis.

Next, we examined the discriminant validity of the scales following Fornell-Larcker criterion. Table 4 compares the correlations among the construct with the square root of the AVE. The values of the square root of the AVE were found to be greater than the inter-construct correlations. Further, the values were greater than the recommended value of 0.707 (Lee and Kozar, 2008). We can therefore conclude that all construct exhibited acceptable discriminant validity.

Table 3: Reliability and Convergent Validity

Construct	AVE	Composite Reliability	R^2	Cronbach's Alpha
ATT	0.694	0.919		0.889
SN	0.567	0.863		0.799
PBC	0.666	0.908		0.873
RB	0.637	0.895		0.851
TR	0.858	0.968		0.958
INT	0.742	0.934	0.369	0.907

Table 4: Latent Variable Correlation Matrix

Construct	ATT	SN	PBC	RB	TR	INT
ATT	(0.833)	0.307	0.476	0.26	0.247	0.455
SN	0.307	(0.753)	0.268	0.301	0.228	0.148
PBC	0.476	0.268	(0.816)	0.221	0.393	0.43
RB	0.26	0.301	0.221	(0.798)	0.238	0.286
TR	0.247	0.228	0.393	0.238	(0.926)	0.357
INT	0.455	0.148	0.43	0.286	0.357	(0.861)

Stage 2: The Structural Model

The next stage was to examine the structural model to determine its explanatory power, and to test the hypotheses of the study. The effects of the construct defined in the proposed model (Figure 1) were assessed through coefficient of determination (R^2), path coefficient (β), effect size (f^2), and predictive relevance (Q^2). It can be observed in Table 5 that the path coefficient for four hypothesized linkages were positive and statically significant (at $p<0.01$). Specifically, the association between subjective norm and intention was statistically not significant, hence H2 were rejected.

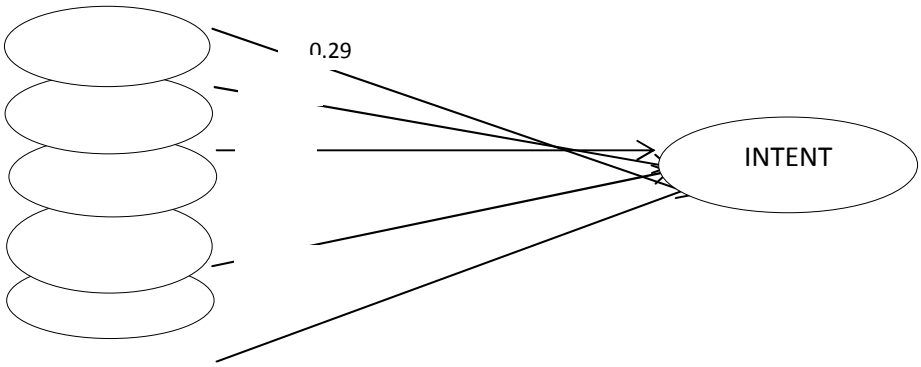

Figure 1: Structural results of proposed model

Table 5: Structural Model Results

Casual Path	Hypothesis	β	p-value	f^2	Supported
ATT-INTENT	H1	0.29	<0.001	0.142	YES
SN-INTENT	H2	0.03	0.276	0.006	NO
PBC-INTENT	H3	0.23	<0.001	0.112	YES
RB-INTENT	H4	0.14	<0.001	0.042	YES
TR-INTENT	H5	0.16	<0.001	0.067	YES

In Table 5 also shows that ATT is the strongest predictor of INTENT, with a path coefficient of .29 (p<.001), which by Chin's (1998), standards which are considered to be strong. From practical point of view, the effect size of the ATT-INTENT path further shows that the effect of ATT-INTENT,PBC-INTENT,RB-INTENT and TR-INTENT was small with f^2=0.142,0.112,0.042 and 0.067 respectively.

5.0 Conclusions

The primary objectives behind this research were to empirically test the extended TPB model and to investigate charitable giving intentions among Malaysians. The current study led to several noteworthy findings. First, the data supported the relationship between attention, perceived behavioural control, religious belief and trust with intention to undertake charitable giving. In this study subjective norm do not influence Malaysian to undertake charitable giving, this is due to that they are not conveyed by others, both by individuals and through the response of a group Bidin et al.(2009).

Interestingly, when compared to the other construct, attitude with a path coefficient of .29 (p<.001), made the strongest contribution to the variance in intention for Malaysian to undertake charitable giving. Thus this shows that when a person has positive attitude towards a specific behavior, they will be likely to perform the behavior (Ajzen,1991,2006;Cheng et al.,2006; Han et al., 2010). The second strongest contribution is perceived behavioural control with a path coefficient of .23 (p<.001), and this shows that Malaysian perceptions of their ability to perform a behavior and also based on the individual feeling of having control over their own bahavior in making charitable giving.

In this study shows that religious belief and public trust is another factors that influence Malaysian to undertake charitable giving with a path coefficient of .14 and .16 (p<.001) respectively. Although both influence Malaysian to undertake charitable giving, but their impact size is different and this shows that trust gives impact more on intention to undertake charitable giving with (f^2=0.47) compared to religious belief (f2=0.42). This is due to Malaysians tend to make charitable giving . if they know what happens exactly to their donations, how much is saved for overhead costs, and where the money is actually spent.

6.0 Limitation and Future Research

Despite several strengths such as sampling a non-student population, robust statistical techniques, and sound theoretical base, the study has some limitations. First, the data collected has not been noted that people from all religions donate but across the religions differences have not been explored (Ranganathan and Henley, 2008). Religiosity is an excellent avenue for future research in the area of charitable giving. Second, the data has been collected from the city of Kuala Lumpur which may not be representative of the whole country populations. Third, the time horizon of this study is cross-sectional which may not represent the differences of opinions over a period of time. There are many events as well as disasters which can change the attitude and ehavior of donors. Future researches are recommended to also conduct longitudinal studies to uncover differences in donations intentions over a period of time.

Nurjannah Salleh, Universiti Teknologi MARA, Melaka, Malaysia, nuurjana@gmail.com

Abstract

Being dependent on the public for funding, a transparent charity organization will more likely to gain confidence from potential donors. This paper focuses on waqf institution, a religious-based of charity organization. Waqf is an Islamic endowment. Waqf can be in the form of cash, property or assets that one donates for the social benefit of the society. Diverse examples of waqf asset include religious buildings, schools, cemeteries, orphanage, commercial and residential buildings and also fund for maintenance. The provision of waqf provides the giver with eternal reward as long as the waqf continues to benefit others either directly or indirectly. The perpetual nature of waqf makes it a highly effective platform for sustainable economic growth. Though many waqf organizations are private in nature, this paper examines transparency in state-owned waqf organizations in Malaysia. Waqf organizations in Malaysia are under the purview of state authorities. Each states set up its own authority to manage waqf. The trustee of waqf in Malaysia are managed by State Islamic Religious Councils (SIRCs). There are fourteen SIRCs each managing their own waqf organizations. This paper examines the information available on the websites of 14 state waqf organizations in Malaysia using content analysis approach. This study examines information on financial, management and media available in the organizations websites. As for the findings, most websites only provide basic organizational information, while financial matters such as collection and usage of fund were quite limited access. Information availability varies significantly among waqf institutions.

Keywords: Charity, Waqf Organizations, Transparency, Web Content Analysis

Introduction

Islam encourage their followers to practice altruism through *waqf* (Islamic Endowment) because of its roles to support religious and philanthropic activities (Hasan & Shahid, 2010). Being a Non Profit Organization (NPO), waqf institution efficiency cannot be judged by the profit criterion alone since they are not profit. Despite the vast size of waqf land, available statistics reported only 40% of waqf land in Malaysian were being utilized and most of it is for cemeteries, mosques and education (Ahmad, 2004). Locations of waqf land that are not strategic and uneconomic size contributed to the predicament. This situation highlighted some of the problems in managing waqf in Malaysia. The most frequent use of *waqf* revenues is spending on mosques, schools, orphan houses, poor, travelers, salaries of imams, salary of the other staff, Islamic preachers and others. The educational sector has been the second largest user of waqf revenues. Other social objectives include generating benefits for the needy and contributing towards wealth and prosperity, socio-economic development of the community and social progress. Waqf institution has potential to contribute to the development of shariah compliant socio-economic of projects as business centers and social projects such as orphanage and care centers (Hasan & Shahid, 2010).

This paper analyzes the function of internet in enhancing transparency of waqf organization. This research utilized web content analysis to examine the prevalence identified communicative and advocacy construct in waqf organization websites. Websites provide a platform for waqf organization to facilitate relationship with stakeholders such as donor, clients and others (Guo & Saxton, 2014). Waqf institution can increase their performance by adopting better financial and corporate disclosure through the use of the internet (Garay et al, 2013). The extent of internet disclosure can also increase

waqf corporate performance (Andrikopoulos et al, 2013) by providing information for investors and provide information access to all stakeholders (Wertheim, 2000).

This paper has twofold objectives. Objective is to examine the issues relating to transparency in waqf institutions. This is achieved through survey of various literatures and study undertaken concerning waqf institutions. The suggested framework proposes a guideline and suggestion for an effective waqf institution. This paper is divided into four sections. The first section underlines the background of study. The next section review synthesis the relevant literature, methodology and result. A final section concludes the paper.

Waqf Land in Malaysia

Waqf or Islamic endowment is an instrument used to retain certain property or asset for philanthropic purposes. Waqf is a provider for continuous and sustainable charity. Since religious matter falls under the purview of State authorities rather than Federal, waqf institutions in Malaysia are governed by State Islamic Religious Councils (SIRCs). There are fourteen SIRCs in Malaysia. It is estimated in 2010 there were 28,444.3 acres of waqf land worth USD580 million however, only 0.72% of the land were developed. The waqf assets are not successfully utilized as intended by the donors. Various factors contributed to the inability to fully develop the assets. Factors such as unfavorable location of assets, weak management and lack of accountability were identified as reasons why waqf assets were unable to generate positive returns to stakeholders (Hisham et al, 2013; Ihsan & Ibrahim, 2011; Rahman *et al.* 2006).

Data on waqf assets are quite difficult to access due to most of the data were not kept properly or deemed confidential by the waqf authorities. Table 1 shows statistic of waqf land in the state of Selangor.

Table 1. Usage of Waqf Land in Selangor, 2008.

No.	Type of usage	Size (acres)	Percentage (%)
1	Utilized waqf land	568.33	53.45
	Mosques	(462.62)	(43.5)
	Surau	(41.17)	(3.8)
	Cemeteries	(2.59)	(0.2)
	Schools	(50.58)	(4.75)
	Charities/Orphanages	(11.36)	(1.0)
2	Unutilized waqf land	494.91	46.54
3	Total waqf land	1,063.25	100

Source: Majlis Agama Islam Selangor, MAIS (2008).

Table 1 shows that the 53.45% of waqf land were utilized in the state of Selangor. More than 90% of the utilized waqf land were for religious purposes and the remaining for school and other charities (11%). Unutilized waqf land accounted for 46.54% of total waqf land. Waqf land are unutilized due to factors such as less strategic location, uneconomic size and scattered in different places. Furthermore, previous studies identify lack of expertise, lack of financial support, incomprehensive law, inadequate disclosure and poor accounting practices were obstacles in developing the waqf assets (Hisham et al, 2013; Ihsan & Ibrahim, 2011). Restricted classification of waqf land mainly for religious purposes deters potential investors and donors to develop waqf land (MAIS, 2008).

Waqf governance

Governance is the main of instrument in any organization for them to achieve their corporate goal. It is a concept that emphasize ethical virtue as transparency, equity, fairness, responsibility, accountability, prudence, participation and responsiveness to the need of the people and efficiency in the management (Hamid, 2008). From the perspective of NPOs, governance is synonymous with

improved performance. In its absence may hampers their role in and applicability in achieving the desired goal on social economic growth and society. However the existing governance framework needs furthers enhancement and improvement. Literature show that there is lack of attention that received by stakeholders and also governance that relate to the conflict of needs and objectives between stakeholders (Wellens & Jegers, 2014).

In addition, the board members of NPOs still lack in promoting good governing, similarly it is suggested that waqf organization to have their own specific governance framework to guide them to engage with good governance in order to achieve good governance for the benefit of waqf institution and their stakeholders (Arshad et al, 2014).

Transparency In Waqf Institution

Transparency is the most critical ingredient in good governance that can be defined as openness, which allowing others to know what is going on and what has done previous involving process that carrying out a task with sincerity, honesty and selflessness in order to achieve desire objective (OECD, 2004). Transparent is generally regarded as a key requirement for successful feedback systems and good governance (Burger & Owens, 2010).

Current management, accounting and reporting practices in waqf organization can helps in determine the scope and size of transparency. This is to ensure that waqf organization practices are shariah compliant. This in turn ensures the socio-economic objectives of waqf are met (Nahar & Yaacob, 2011). In addition, the use of current technology is recommended in establishing transparency in organizations. An independent media is a route to enhance transparency. Web is an agent of independent media that ables to promote transparency and strengthen social control by exposing acceptance of standard behavior to public view (Hamid, 2008).

Waqf organization itself abide by Islamic conducts in managing waqf assets in order to fulfill their accountability to Allah. Concurrently, accountability in fulfilling waqf objective will ensure that waqf contribute to expansion of muslim communities (Ihsan & Ibrahim, 2011). Furthermore, a clear and transparent reporting will enable stakeholders to ascertain whether organizations have fulfilled their accountability. The report will also portray how compliant waqf organization are to the shariah rules in managing waqf assets (Nahar & Yaacob, 2011). Fully transparent culture in waqf organization can be achieved by applying open communication though management, financial or any relevant media sources such as website, magazine or annual report (Salvatico, 2006: Burger & Owens, 2010)

Waqf organization website disclosure

Website disclosure defined as the material provided on public website that show organization innovative practice that voluntary disclosure. Financial and performance level of organizations are two important components of disclosure sought by stakeholders (Lee & Joseph, 2013). Financial disclosure includes annual report or audited financial statements while performance disclosure includes organization mission and vision, performance goal and outcome, success stories, communities' impact, staff list or broad list. Organizations that had higher disclosure are more likely to be successful compared to organization that applied lower disclosure

Not only disclosure increase transparency, it is also more likely to improve future contribution by donors (Gandia, 2011). Besides, disclosure can decrease the opportunity for selfish motive that could encourage the exploitation of weakness in information flow and feedback system (Djankov *et* al., 2008). Through disclosure, organizations are able to provide information to potential clients, members, donors and volunteers. Organizations are also able to provide basic data for research and establish norm for peer organizations (Bothwell, 2004).

Despite the advantages of being transparent, misleading information disclosed by organizations in lieu of favorable view from the audience is a main concern. Providing information also depends on willingness and the ability of organizations (Burger & Owens, 2010). Absence of regulatory body

hampered the desired level of disclosure and uniformity in the industry (Wertheim, 2000). Furthermore, web vulnerability or network database leakage compromise organizational security limits information disclosed by organizations (Cho & Pan, 2015). Organizations websites only provide their basic information, scope, issues around organizations and periodical management report (Lopes, 2014). This incomplete development of information directly inhibits the role of website as stage to improve transparency (Cho & Pan, 2015). Most waqf organizations are not adhering to the best practice guidelines.

Methodology: Web content analysis approach

Internet is a platform for organizations to communicate their message and information to the public. It provides an incredible opportunity for audience adaptation and personalization any messages and the World Wide Web is clearly more efficient than dyadic interaction. Although many people lack Internet access, millions are connected, and number of potential audience increasing daily. Using the Internet to disseminate messages involves less cost than other media in terms of time, personnel, and money.

As of 2012, 65.8% of Malaysian population had access to internet and the ICT Development Index (IDI) for Malaysia has increased from 66% (2012) to 71% (2013) (SKMM, 2014). This study examined the information available on website organization using web content analysis approach by Krippendorff, 2004. Web analysis process included discourse analysis to study web content. Focus of the analysis is on web as socio-cultural 'texts' and it described and explored from a qualitative perspective to uncover underlying meaning and significance (Gibson, n.d). This web-based media require methods of analyzing form and content, along with processes and patterns of production, distribution, usage and interpretation Content analysis is a wide and varied of manual or computer assisted techniques for contextualized interpretations of documents produced by communication processes of any kind of text, written, iconic, multimedia, and others or signification processes, having as ultimate goal the production of valid and trustworthy inferences (Tipaldo, 2014).

Data collection

Data was collected through accessing all 14 SIRCs websites. Data on transparency characteristics of the websites were recorded. Transparency information revealed on the websites are recorded through a measurement proposed by the Sunshine Review (2013) and Lowatcharin & Menifield (2015). The Sunshine Review had developed a "7 point transparency checklist" including, budget, meetings, elected officials, administrative officials, permit and zoning, audits, contracts, lobbying, public records and local taxes. The websites will be awarded 7 points if all information are provided in their web pages.

Result

All fourteen websites were analyzed, however none of the websites succeed to fulfill all the criteria. Only two SIRCs obtained a score of six out of the maximum seven. Majority (6) of SIRCs scored five out of seven points. Three SIRCs provided less than half of the information listed on the disclosure checklist. Data presented on the last date of web access which is 27 February 2015.

NS	Negeri Sembilan
FT	Federal territory
AO (Administrative official)	Contact information, organization chart and number of staff in waqf unit.
B (Beneficiaries)	The information of person that received benefit from waqf.
S (Source of waqf)	The information of waqf sources.
Au (Audit)	The information of WAQF audit process and output.
AR (Annual Report)	The information of yearly end report.
I (Information)	Consist of Waqf basic information.
Ac (Activities)	The information of activities or projects that used waqf fund.

Activities and basic information on waqf are the information readily available on almost all SIRCs websites. The next most available information is contact number of waqf staff. Eleven (78.5%) SIRCs provided information that includes staff full name, their position, telephone number and email address. Headcount on the number of staff discovered that waqf institutions in Malaysia has a total 131 staff. However, evidence from visits showed that most of SIRCs shared their staff among departments. For example, a staff might be entrusted not only to waqf department but also to other

departments in the SIRCs. Obviously this has a strong bearing whether a staff can really contribute to the development of waqf. Only eight (57%) SIRCs posted their waqf organization chart online.

Eight (57%) SIRCs websites provide information on sources of waqf fund. The information however is general in nature, no specific information on donors and amount of donation were disclosed. Access to such information are considered as classified. Seven (50%) of SIRCs websites provided information on beneficiaries and types of benefits given. Again, the information are in general with no specific details on recipients provided.

Only four (28.5%) of the SIRCs exhibited information on audit. The information provided however are on details of audit staff such as job scope, position and contact information. Information on audit activities were not available. Three (21.4%) SIRCs, namely the Federal Territory, Selangor and Negeri Sembilan posted their yearly end reports on the websites. Although reports on waqf are minor part of SIRCs report, it's an important contribution in securing confidence from stakeholders including donors. Annual reports provide information on organization's financial health and can attract support from donors (Liket & Maas, 2015). Apparently, the three SIRCs that published annual reports are among the more developed SIRCs in Malaysia.

Conclusion

Responsive organization systems are labeled as part of good governance. The development of waqf governance improve effectiveness and efficiency of waqf organization. Disclosure enables waqf organization to develop productive relationship among public, beneficiaries and trustees. It also enhances cooperation and contribute to improvement of waqf administration. Increase disclosure also translates to greater transparency, better management and increase public trust. Advent of modern and sophisticated information technology system such as the establishment of websites, promotes greater disclosure and transparency in organizations.

Overall, the study found that the disclosure among SIRCs as far as waqf matters are concern are still low. This is evident by types and lack of depth of information disclosed on the websites. Information on financial and organizational performance ranked the lowest among types of information disclosed. Level of disclosure varies among SIRCs. High disclosures, as evident in the websites, are associated with SIRCs which exhibit better management of their waqf institutions.

Résumé

Alors que le texte occupe une place importante sur les sites web, cette étude dresse un état des lieux actuel des différentes typographies utilisées. Sur la base d'une revue de travaux fondateurs et un audit typographique de 58 sites web, cette recherche exploratoire discute les principales caractéristiques typographiques choisies par les designers de ces sites et en fait le rapprochement avec les travaux théoriques portant sur la typographie.

Nos résultats mettent en évidence un réel gap entre les pratiques des concepteurs et la revue théorique. Ainsi, nous tentons d'expliquer ce fossé et donner des pistes pour les travaux futurs, afin de le réduire.

Mots clés : typographie, lisibilité, esthétique, commerce électronique

THE TYPOGRAPHY OF WEBSITE: BETWEEN THEORY AND PRACTICE

Abstract

While text occupies an important place on websites, this exploratory study provides a current state of play of the use of different fonts by French websites.
Based on a review of pioneering works, and a typographical audit of 58 websites, this exploratory research discusses the main typeface chosen by theses website's designers and establishes a connection with theoretical works on typography.
Our findings highlight a real gap between designer's practices and our theoretical review of the literature. Thus, we try to explain this gap and also provide ideas for future researches, in order to reduce it.

Keywords : typography, legibility, aesthetics, electronic retailing

Introduction

Sur les sites web marchands, les contenus d'informations sont majoritairement de nature textuelle. Ainsi, il est important d'accorder une grande attention à la typographie. Le choix des polices, de la taille, de la mise en page des différents contenus au sein des pages web, mais aussi le sens donné à la rédaction, tous ces paramètres s'inscrivent ainsi dans une démarche d'utilisabilité, d'accessibilité et d'ergonomie, enjeux essentiels pour l'amélioration de la qualité des sites web.

Il est important de noter que la lecture du contenu reste l'activité principale de l'internaute sur le web. Cependant, elle est beaucoup moins confortable que sur papier, et il a en effet pu être mis en évidence

que la vitesse de lecture sur un écran est sensiblement moins rapide que celle que l'on observe sur un support papier[1] (Nielsen, 2013).

Dans ce contexte, plusieurs travaux de recherches se sont intéressés à la typographie afin d'optimiser la lisibilité du texte sur le web, comprendre son impact sur le comportement du consommateur, mais aussi de mettre à disposition des responsables marketing les principaux ingrédients théoriques requis pour favoriser l'amélioration de l'expérience de l'utilisateur. Or, malgré la richesse des implications théoriques issues des travaux de recherche, 74% des Français préfèrent encore lire en version papier même si la plupart des informations qu'ils contiennent sont accessibles en ligne[2] (Cabinet Deloitte, 2013).

De ce fait, la question des relations entre théorie et pratique est au centre de notre recherche. Elle est souvent abordée sous l'angle de l'utilité des recherches pour les managers, et l'accent est plutôt mis sur le décalage entre théorie et pratique. L'ambition de cet article est d'interroger les liens théorie-pratique en terme de choix typographique. Réactualiser ces données et développer une meilleure compréhension des choix des designers apparaît essentielle afin de mieux sensibiliser les chercheurs sur les pratiques professionnelles et renseigner les responsables des sites sur les stratégies à adopter.

Dans cette perspective, nous montrons en premier temps les principaux travaux théoriques portant sur la typographie, et puis dans un second temps, nous mettons en œuvre un audit typographique de l'utilisation des différentes typographies par les sites web en France. Et nous terminons par donner des pistes pour les futurs travaux de recherches.

1. Le cadre conceptuel de la recherche

Selon Médiavilla (2006), la typographie peut être définie comme « l'art de composer et de mettre en pages les textes». Pour McCarthy et Mothersbaugh (2002), la typographie fait intervenir trois facteurs : les caractéristiques de la police, l'espacement et la mise en page.

- *Les caractéristiques de la police* : elles rassemblent les éléments qui affectent l'apparence concrète des formes des lettres. Elles incluent le style de caractère, la taille, la hauteur du corps, la graisse, l'inclinaison, le soulignement, la couleur, et dans le cas des médias électronique, ils rajoutent « le mouvement » comme sous-dimension de la police. Il est intéressant de noter qu'il existe de nombreuses polices de caractères et de nouvelles ne cessent d'apparaitre chaque jour. De ce fait, des classifications ont pu être proposées. La plus connue est celle établie par Maximilien Vox en 1954 et adoptée par l'Association typographique internationale depuis 1962. Cette classification se compose de 11 familles de polices de caractères regroupées en fonction de caractéristiques physiques communes (l'empattement[3], l'axe d'inclinaison[4] et la hauteur d'x[5]). Par exemple, la famille des linéales regroupe les polices sans empattement et la famille des humanes est caractérisée par des polices utilisant les empattements. Par ailleurs, les Scriptes, les Manuaires et les Fractures présentent la particularité d'imiter l'écriture manuelle ou calligraphique.

- *L'espacement* : il correspond à la distance existant entre les lettres, entre les mots, et entre les lignes de texte.

- *La mise en page* : elle regroupe la longueur des lignes, le nombre de colonnes, le cadrage du texte et l'homogénéité ou le contraste du texte par rapport à la page web dans son ensemble.

1.1. Le rôle de la typographie : de la lisibilité à l'esthétique

La typographie est à la fois mot et image. Elle se situe entre le langage verbal et le non verbal. En effet, trouver un juste équilibre entre esthétique et fonctionnel est nécessaire. Selon Stôckl (2005), les polices de caractères possèdent une dualité dans leur nature car elles ont en premier lieu pour objectif de respecter les conventions typographiques afin de rendre un texte plus lisible. Ainsi, en utilisant les

signes visuels conventionnels pour écrire, la typographie rend le texte reconnaissable et fonctionnel. D'autre part, la typographie possèdent des aspects iconiques qui offrent une apparition beaucoup plus joueuse avec le signe écrit en allant chercher tout son potentiel pictural (Stôckl, 2005). Cette propriété s'opère par l'usage de plusieurs procédés typographiques tels que: la direction des lignes, la mise en pages...etc.

1.2. Les effets des caractéristiques typographiques sur la lisibilité et l'esthétique

Les premiers travaux portant sur la typographie des sites web étaient souvent exploratoires en s'intéressant à **la lisibilité** des pages web. De ce fait, Hill et Scharff (1997) ont fait varier deux combinaisons de **polices**, en plus de faire varier six couleurs. La meilleure lisibilité a été obtenue avec le texte de couleur vert sur fond jaune quand la police était du Times New Roman (police avec empattement). En revanche, en utilisant cette même charte graphique avec la police Arial (police sans empattement), le résultat était beaucoup moins bon. Ainsi, Ovink (1938) et ensuite et al. (1971) ont
trouvé que l'empattement était utile car il avait un rôle décoratif et un effet sur le traitement visuel. Les empattements permettent de distinguer facilement les lettres. La lettre « i », sans empattement est notée « i », la similitude avec le « l » dans la même fonte est intense.

Concernant la taille, certaines études soulignent qu'elle a peu d'effet sur la lisibilité. Tinker (1965) et Zachrisson (1965) constatent que les tailles de 8 à 12 points ont un rendu de lisibilité semblable.
Tout comme les caractéristiques de la police, **la mise en page** peut affecter la lisibilité de la page web. Les recherches passées ont montré les lignes de texte comportant de 40 à 70 caractères peuvent être lues sans difficulté. Au-delà ou en deçà de cet intervalle, la longueur des lignes pourrait affecter la vitesse de lecture car cela nécessite plusieurs sauts visuels pour passer d'une ligne à une autre (Bastien, et al. 1998 ; Bernard 2003 ; Schneiderman, et al. 2006).

Les caractéristiques de **l'espacement** semblent aussi pouvoir affecter la lisibilité. Des caractères trop près les uns des autres sont difficiles à différencier et rendent la lecture difficile. Ainsi, des caractères trop espacés empêchent le regroupement des lettres pour former les mots ; la lecture est alors ralentie. De ce fait, Ambrose et Harris (2008), insistent sur l'importance d'un bon réglage de l'interlignage et recommandent l'utilisation d'un interligne plus large que la hauteur de la police. En deçà de cette hauteur, le texte paraît compressé, et au-delà, la composition est incontestablement aérée et l'œil du lecteur est perturbé, car il doit faire un saut d'une ligne à l'autre.

En ce qui concerne l'aspect **esthétique** véhiculé par la typographie, les caractéristiques typographiques peuvent affecter l'apparence en influençant la physionomie et le sentiment d'ensemble du site web par plusieurs manières. Si on se réfère à la théorie de la forme, et notamment au principe de symétrie, on peut se rendre compte que des lignes de texte très déséquilibrées peuvent donner un sentiment d'une page déséquilibrée et donc entrainer une attitude négative vis-à-vis de cette page. De même, le principe d'unité de la théorie de la forme suppose encore que l'utilisation de polices non homogènes entre les masses de texte peut créer un manque de cohérence, ce qui peut conduire à une attitude négative vis-à-vis du site (McCarthy et Mothersbaugh, 2002).

2. Méthodologie

Afin de dresser un état des lieux actuel et complet de l'utilisation des différentes typographies par les sites web en France, et analyser les évolutions par rapport aux travaux cités en théorie, une analyse typographique a été effectuée sur 58 sites. Le choix des sites s'appuie sur les critères suivants : une diversité de catégorie de produit et ou service, le volume de fréquentation et préférence par les Français en 2014[6] Nous citons à titre d'exemple les sites suivants: Amazon, Cdiscount, booking.com, billetreduc.com, voyages-sncf.com, vente-privee.com, lemonde.fr...etc.

L’analyse concerne 6 secteurs d’activités : sites de voyages-tourisme, sites de vente de vêtements, sites d’actualités et d’informations généralistes, sites de cinéma, sites féminins et enfin sites de guides de sorties et loisirs.

Les sites Internet ont été audités sur la base d’une grille d’analyse qui observe les principales dimensions de la typographie : style de caractère, type de polices, nombre de polices, taille de caractère, interlignage et la longueur des lignes.

3. Résultats et discussion

Tableau 1: type de police de caractères utilisé par les sites web

Type de police	Effectif	Pourcentage
Sans empattement (sans sérif)	54	93%
Avec empattement (sérif)	4	7%
Total	58	100%

A la lecture du tableau (1), nous relevons que la majorité des sites web (93%) préfèrent l'utilisation des polices sans empattement. Il y a deux raisons pour cette tendance :

- Un caractère avec empattement produit des « effets d’escalier » sur sa base qui rend la lecture plus difficile sur le web contrairement à l'imprimé où les recherches passées ont démontré que le style sans empattement est plus facile à lire (Burt, 1959, 1960).

- La résolution d’un écran est beaucoup plus faible que celle du papier. En conséquence un caractère avec empattement risque de produire un effet de flou qui rend la lecture plus difficile.

Tableau 2: les principales polices de caractères utilisées par les sites web

Police de caractères	Effectif	Pourcentage
Arial	33	57%
Helvetica	5	9%
Tahoma	5	9%
Georgia	4	7%
Verdana	3	5%
Trebuchet MS	2	3%
Autres polices de caractère	6	10%
Total	58	100%

Le tableau (2) montre que la police la plus utilisée pour le texte courant est l'Arial (57%), suivi de l'Helvetica (9%) , Tahoma (9%) et ensuite le Georgia à (7%). Contrairement à ce recommandent Hill et Scharff (1997), nous n'avons relevé aucun site qui utilisait la police avec empattement Times New Roman.

Les résultats ont établi également que 57% des sites utilisent au minimum deux polices différentes. Les recherches en théorie ont démontré que des variations dans les caractéristiques de la police entrainent des différences significatives au niveau des associations sémantiques (Bartram, 1982; Rowe, 1982). De même, par le principe d'intensité de la théorie de la Gestalt, les objets similaires et/ou proches ont plus de chance d'être perçus comme une unité cohérente, et les objets différents et/ou distants comme des entités séparées. Par conséquent, l'utilisation de plusieurs polices non harmonisées peuvent donner le sentiment que le texte est désorganisé et incohérent. Ces sentiments négatifs pourraient entrainer des comportements d'évitement.

Tableau 3: tailles de caractères utilisées par les sites web

Taille (Pixels)	Effectif	Pourcentage
12	21	36%
13	9	16%
14	8	14%
16	6	10%
15	5	9%
11	4	7%
17	3	5%
18	2	3%
Total	58	100%
Moyenne	***13,5***	

Pour ce qui est de la taille de caractère, le tableau 3 montre que la taille de caractère la plus utilisée (36%) est de 12 pixels. Néanmoins, l'analyse illustre l'existence de divergences importantes dans la mesure où 18% des sites affichent des tailles supérieures ou égale à 16 pixels. En théorie, les effets de la taille du corps sur la lisibilité sont controversés : l'effet mis en valeur est soit monotone soit en U inversé (Mc Carthyet Mothersbaugh, 2002). La taille de la lettre et sa capacité à être distinguée au sein de la police sont deux facteurs décisifs. La taille est importante, du fait des limites de nos systèmes de perceptions, les stimuli doivent être de taille suffisante pour être facilement perçus et traités. La capacité à être traitée, est importante car, comme Tinker (1963) l'a montré, beaucoup de lettres (c'est à dire c, e, s, o, i, n) sont généralement peu lisibles, alors que d'autres lettres partagent des formes communes et sont différenciés seulement par différences mineures (par exemple i et l). Si les lettres sont trop petites, la reconnaissance des mots est très difficile. En revanche, une fois que les lettres sont d'une certaine taille, elles sont assez grandes pour être facilement reconnues, quelle que soit leur capacité à être distinguées.

Tableau 4: longueur moyenne des lignes utilisées par les sites web (nombre de caractères par ligne)

Secteur	Moyenne
Voyages-Tourisme	104
Guides de sorties et loisirs	95
Actualités, informations généralistes	91
Sites Féminins	90
Vente de vêtements	87
Cinéma	80
Moyenne globale	**91**

Concernant, la longueur des lignes, Shaikh (2005) montre qu'elle influence la préférence du texte quand il est présenté sur un écran d'ordinateur (préférence pour les lignes les plus longues ou les plus courtes). Les résultats de l'audit des sites qui ont fait l'objet de l'étude montrent qu'une ligne comprend en moyenne 91 caractères. Néanmoins, la longueur de lignes a aussi un impact sur la lisibilité. Paterson et Tinker (1940) observent que l'optimum de la longueur d'une ligne se situe aux alentours des 75-90 millimètres soit approximativement 60 caractères de taille de 12 pixels. En-deçà et au-delà de cette limite, le temps de passage d'une ligne à une autre altère la vitesse de lecture.

Les auteurs ont également étudié l'interaction entre la longueur de ligne et l'interligne. Ainsi, plus la ligne est longue, plus l'interligne doit être important. Becker et al. (1970) affirment que chaque fonte a un type d'interligne idéal. En se basant sur ce dernier point de Becker, nous avons calculé l'indice (Interlignage/taille de la police). Ainsi, *l'interlignage moyen* est de **1.3 fois** le corps avec un écart-type de 0.2. Cette hétérogénéité dans les choix des professionnels nous amène à nous interroger sur la

facilité de passage d'une ligne à une autre lors de la lecture et aussi sur l'apparence de la page web. En effet, la physiologie de la lecture suggère qu'un espacement réduit entre les lignes conduirait à des chevauchement entre des lignes successives, ce qui devrait réduire la différenciation des lettres et par là la lisibilité. Cependant un grand espace entre les lignes n'est pas forcément meilleur car il peut augmenter la difficulté à passer de ligne en ligne et donc augmenter le temps de fixation oculaire sur les mots et réduire la rapidité de lecture (Bentley, 1921).

L'interlignage peut aussi affecter le look et le sentiment général crée par le texte. Un plus grand espace entre les lignes augmente la surface prise par le texte et donc accroit la perception qu'il y a davantage de texte. Des études ont montré d'ailleurs l'effet négatif de la longueur du texte sur le lectorat (Finn, 1988). A titre illustratif, le site d'information *Lci.tf1.fr* qui fait partie de notre échantillon d'étude affiche en haut à droite sur chaque article le temps de lecture pour minimiser la probabilité de fuite de l'internaute.

Enfin, nous découvrons également que plus de 81% des sites ne justifient pas à droite et à gauche leur texte. La pratique quasi-généralisée est d'aligner le texte à gauche et de le laisser flotter à droite, ce qui altérerait l'aspect esthétique du site car selon le principe de symétrie de la Gestalt : une longueur de ligne ou une largeur de colonne déséquilibrées sont déplaisantes et suscitent des attitude négatives vis-à-vis du site web.

4. Apports et conclusion

Cette étude et ses résultats présentent des contrastes intéressants entre les travaux théoriques et les usages des professionnels. Il est intéressant de noter que ces résultats confirment l'existence d'un gap entre les recommandations des chercheurs et les typographies utilisées sur les sites web. Il nous semble que les recherches passées donnent des explications sur la façon dont la typographie affecte la lisibilité des textes et l'esthétique des pages. Cependant, des travaux de recherches complémentaires sont indispensables pour plusieurs raisons :

a) D'abord, les études précédentes se sont limitées principalement à l'impact de la typographie dans un cadre offline, en se focalisant principalement sur l'imprimé et n'ont pas pris suffisamment les spécificités de la lecture sur le web. Il important de souligner que malgré l'existence de l'ensemble des dimensions de la typographie sur le web, le comportement de lecture de l'internaute est relativement différent. En effet, selon Baccino et Drai-Zerbib (2015), les différences fondamentales entre support papier et le web portent sur quatre facteurs :

- *Le mode d'éclairage* : il est extrinsèque dans le cas de la lecture papier, mais provient du support lui-même dans le cas de la lecture sur écran. Ce rétro éclairage pouvant être source de fatigue visuelle alors que le papier offre un confort visuel maximum même si actuellement, les technologies tentent de remédier à ces insuffisances par l'amélioration des définitions des écrans.

- *L'activité de lecture* : elle est linéaire et continue sur le papier, alors que sur le web c'est plutôt une lecture de scan.

- *Le contenu sensoriel* : sur le support papier, l'information peut provenir de deux sources, le texte ou l'image, alors que le web peut y émettre le son, la vidéo qui pourraient impacter l'expérience de lecture. Par ailleurs nous pouvons supposer l'existence des interactions entre ces stimulus, comme la typographie et la musique sur le web, qui est techniquement impossible sur le papier.

- *Le mode de présentation* : Elle est fixe sur l'imprimé, et dynamique sur écran par l'utilisation du défilement permettant de naviguer sur le web de haut en bas ou l'inverse.

b) Ensuite, la typographie pour le web serait à la fois un héritage de la typographie classique, et une adaptation aux contraintes nouvelles liées à la machine et au comportement de lecture de l'internaute. C'est donc une question d'adaptation et d'adhésion à la flexibilité du web. Pour cela, nous pensons qu'il nécessaire, de réaliser des recherches exploratoires pour identifier la perception des internautes

de la typographie du site web, comprendre son impact sur l'expérience de lecture, et explorer ses effets sur états émotionnels et comportementaux.

c) Enfin, parmi les facteurs explicatifs de ce gap est que, les études précédentes ont été réalisées avant le développement technologiques, notamment le CSS3[7], qui permet un examen précis de variables éventuellement associées. Les recherches passées se sont plutôt focalisées sur la dimension « police » séparément des autres facteurs, sans prendre en considération l'éventuelle existence de fortes interactions entre les composantes de la typographie (Mc Carthy et Mothersbaugh, 2002 ; Wheildon,1995 ; Becker et alii, 1970).

Nos résultats comparatives montrent qu'il est nécessaire de développer plus d'éléments théoriques relatifs à la typographie des sites web afin de mettre évidence l'influence de cette variable et aider les managers à choisir la typographie la plus appropriée à leurs sites afin d'améliorer l'expérience de l'utilisateur.

Notre étude est également l'occasion d'attirer l'attention sur une composante atmosphérique des sites web peu étudiée jusqu'à présent dans la littérature. Cette recherche apporte par ailleurs un éclairage aux chercheurs voulant explorer ce champs de recherche en mettant à leur disposition un état de lieu actuel de l'utilisation des différentes typographies par les sites web.

Sur le plan managérial, les éléments de cet article fournissent quelques résultats théoriques des recherches passées, qui pourraient aider les professionnels à mieux cerner cette variable lors de la conception de leurs sites. Ainsi, la typographie a un rôle fondamental à jouer au niveau des interfaces de sites web marchands. C'est l'un des éléments du design qui a le plus d'influence sur la lisibilité et l'apparence esthétique du site web. Au vu de ces points théoriques, il semble important que les managers soient conscients des effets de leurs choix typographiques sur la lisibilité et l'esthétique perçues de leurs sites web.

Bien que de nombreuses précautions aient été prises, les conclusions auxquelles nous sommes parvenus dans cet article méritent d'être relativisées compte tenu de la nature exploratoire de notre recherche (taille et composition de notre échantillon).

En termes de voies futures de recherche, il serait intéressant d'étendre l'étude à d'autres sites web dans différents pays, et de mener des recherches qualitatives et expérimentales visant à tester les relations qui unissent les dimensions de la typographie aux réactions des internautes.

Individual Human Resource Management and Development: Career Management

Viviana Meirinhos[1] & Susana Silva[2]

[1]Polytechnic of Porto, Centre for Human Resources Research and Development (NID_RH), Portugal, vivianameirinhos@eseig.ipp.pt
[2]Polytechnic of Porto, Centre for Human Resources Research and Development (NID_RH), Portugal, susanasilva@eseig.ipp.pt

Introduction, Propositions and aim

Framed on a wider project on Individual Human Resource Management and Development (HRMD), this project aims to explore Individual Career Management and Development (CMD) as an emergent professional field of HRMD.

Our conceptual framework working proposition is that HRMD is a field progressively grounded on individual approaches. If traditionally HRMD was mainly theoretically and empirically sustained in collective strategies and practices, contemporarily individual strategies appear to get dominant in all HRMD processes, such as exemplarily in recruiting, selecting, performance management, compensating or training.

In CMD this setting is revealing to be replicated. Managing and developing the career is no longer an exclusive organizational responsibility, in which careers shape and are shaped by organizations. According to the changing nature of career and unstable employment, there is an increasing conceptualization that individuals' career progression is the responsibility of themselves (Enache, Sallán, Simo & Fernandez, 2013).

In this paradigm, people individually become central actors in managing their own careers, what enhances individuals' perceptions of control over their careers (De Vos & Segers, 2013; King, 2004). This career approach is described in terms of individual independence from organizational career management systems, and in terms of oneself reliance. This suggests that individuals are deploying more career self-management activities, and less concerned with career management activities provided by organizations (De Vos, Dewettinck & Buyens, 2006). This career management approach relies on a proactive attitude of the individual towards his career. It involves self-analysis of talents, capabilities, self-awareness, career ambitions, environmental awareness, networking, self-nomination and creating new job opportunities (Weng & McElroy, 2010). Individuals engaged in this perspective are more likely to involve themselves in improvement opportunities, innovative behaviors, and in lifelong learning (Muja & Appelbaum, 2012), developing a more mature CMD and consequently contributing to a more balanced and sustained labor market.

It is our conceptual proposition that this scenario will conduct to a stronger concern about the support individuals receive in realizing career goals. Therefore, De Vos et al (2006) suggest that these individuals will have higher expectations about the practices set up to support their career management and development, namely by Human Resources professionals. These professionals could have a central role in supporting individual career management, since they have specific competencies in assisting others to manage their careers. In practice, HR professionals may stand as the key actors for promoting individuals' career self-management and development (Kahnweiler, 2006).

It is our proposition that this Individual Career Management and Development framework requires new roles and new competencies from the HRMD professionals, claiming consequently new educational contents on HR education and new research questions to be addressed by HR scientific community.

Research objectives

This research specific focus is on:

- Characterizing the theoretical state of art of Career Management as an individual responsibility;

- Developing a functional description of Individual Career Management related professional activities;

- Presenting a conceptual definition and framework for Individual Career Management;

- Building a framework for Individual Career Management as a professional activity within HRMD.

Research Design

To investigate and model Individual Career Management as an HRMD practice requires a comprehensive view of what this practice is. Therefore, in order to accomplish our research objectives, we defined as research design:

- Analyzing current theoretical and empirical research approaching Career Management as an individual responsibility;

- Identifying professional activities related to Individual Career Management;

- Developing job analysis of Individual Career Management related professional activities;

- Consolidating conceptual end empirical data.

Contributions

This research project aims to provide two main contributions to HRMD field:

- To contribute to the identification of research objects and research problems within Individual Career Management;

- To contribute to the identification and promotion of HR educational knowledge within Individual Career Management subject-matter based on emergent HR working knowledge needs.

Conclusion

The aim of sharing this research project within the HR scientific community at this kick off stage is to call for international partnerships to explore this new theoretical perspective on Human Resource Management and Development in the context of its imminent changing role. It is our intention to widen this research to other countries in order to acquire and generate more significant insights into this individual approach to HRMD, in general, and CMD, in particular. This section should follow keywords. This section should provide background of the study and highlight research motivation.

A Model for Analyzing the Expected Revenues Resulted from the Development of New Products within Strategic Alliances

Ana-Maria Giurea, The Bucharest University of Economic Studies, Bucharest, Romania,
ana.giurea@yahoo.com

Abstract

The paper describes a model for analyzing expected revenues as a result of the development of new products within strategic alliances. As the business world faces an increased degree of complexity regarding typologies and firms' motivations, different long-term partnerships can be developed, ensuring a continuous and guaranteed productivity for all partners involved. With the help of the analysis model described in the paper, the equitable profit for the firms within alliances/collaboration, cooperation or partnership agreements can be determined starting with the basic formula of the "return on sales" (ROS). In other words, based on the method for calculating the new value of ROS, the partners will have the opportunity to find out their expected revenues ($V_{i;n}$). To this end, they need to be aware of the total costs that one company needs to allocate in order to develop the group of products in collaboration with its partners. Moreover, they need to know the costs allocated by all of the companies together in order to develop a certain product from the group of products. The model is validated by the implementation of the same price strategy and by the achievement of a well-adjusted management, determined by mutual respect between firms within a partnership.

Keywords: strategic alliances, expected revenues, R&D, ROS

Introduction

The main goal of the strategic alliances is to create growth conditions for the companies on the market. DePamphilis (2015) considered that the role of the partner remains essential within a strategic alliance. If the firms pursue common growth objectives on the market, the partner will offer a source of new information, it will be an assistant needed for developing new products and it will provide the support for continuous development initiatives and perspectives for the other collaborating companies. Pooling resources, information, know-how, technologies as well as allocating significant amounts of money for research and development could represent sources for gaining a step ahead of the competitors, increasing customer loyalty as well as attracting new clients by satisfying their continuously changing needs. Investments in research and development (R&D) (Owen and Yawson, 2015), implementing all of the proposed activities, fulfilling the established objectives, carrying out persuading actions on clients' needs, as well as a proper management of decisions, resources and time could contribute to the maintenance of the partnership's equilibrium. The company may choose its strategic alliance by knowing and being aware of its own competitive advantages on the market and its continuous need for standing out on the market (Brouthers et al 1995). If we were to adapt Marcio Barrios's saying "ambition is the perfect ally of the winner", to the economic world, it would mean that a firm's ambition represents an essential item for its own development. The firm's constant flow of motivation and the acceptance of the idea of collaboration with another firm enable it to achieve its desired objectives, surpass its condition as an individual entity on the market and reach high performance by achieving a leading position on the market and obtaining the proposed results regarding sales.

Strategic alliances

Twarowska and Kakol (2013) had quoted Campbell E. and Reurer J.J (2001) in their paper. They believe that "a strategic alliance represents a cooperative arrangement between firms that targets the research, the establishment of joint ventures or the participation with minor capital". They argue that: "strategic alliances are often encountered between companies from strongly industrialized countries; the purpose of strategic alliances is based on the development of new products and technologies on a

short period of time". Even though it is difficult to quantify the joint ventures' contribution to the Gross Domestic Product, it cannot be questioned that the interest of the firms for these types of alliances is continuously growing. According to economists Chen and Ross (2003) the variety of these types of agreements appears due to the firms' interest for alliances in order to trade and distribute common products, as well as alliances for sharing production capacity (aeronautics industry), technical information exchange agreements, research and development projects.

The establishment of a joint venture consists in a bipolar process by the use of which firms share all types of resources in order to develop a product on a market. In their analysis, economists Chen Z. and Ross T. (2003) develop a pricing strategy for the new company founded by two competing mother companies. They also calculate the impact of the strategy on the downstream chain on the market. The results of the analysis shape the fact that establishing a joint venture is the equivalent of a complete merger between two mother companies because it has an impact on prices, final production and costs. The effect on the market's efficiency will depend on the degree to which the economies of scale compensate the reduced level of competition between the partners. Likewise, another result of the analysis shapes the fact that a firm prefers to enter a new market with the help of an established operator that is vertically integrated, and set up a joint venture agreement, instead of establishing its own supply source. This would lead to low prices and high profits for both the operator and the firm. Furthermore, if the mother firms adopt different pricing strategies and different demand visions, they will have different preferences in case of a joint venture as well, when setting an optimal pricing strategy.

This different approach on prices might generate tension between partners. Therefore, the method for harmonizing the interests regarding the price, that the two economists have developed, is based on adjusting the property shares in a way that if one of the companies has a larger property quota (share) it will be interested in lower prices, and the other firm, holding a smaller property share will choose the higher prices. This case is valid only in the situation where the firms are using similar products. In order to surpass the barriers to entry imposed by the competition on the market, the development of new products remains essential for the firms. Overall, the company itself establishes the lifetime cycle of a firm.

The growth strategies on the market represent one of the most important framework subjects in business literature. In their paper, Romero-Merino and García-Manjón (2012) quote Geroski (1995) and Sutton (1997) who associate the growth on the market with the guarantee of the firm's survival as well as with the establishment of economies of scale. Therewith, Geroski (1995) argued the fact that "the entry (on the market) is easy but the survival isn't". This means that if a firm enters a certain market, it faces the situation of keeping pace with the customers/clients' requests as well as with the competition on the market. In my opinion, I think that a "beginner" on the market, that has no perspective in innovation, research and development or openness towards strategic alliances with other companies, will find it hard to grow on its own simultaneously with its adversaries. Pooling resources and sharing know-how may lead to successful synergies that may provide substantial revenues for the actors involved. Thus, Romero-Merino and García-Manjón (2012) reveal the fact that there is a positive effect of the research and development intensity upon the partners' sales growth. The authors have developed regressions and system estimators for a sample of 754 European firms for a period of 4 years, between 2003 and 2007. They have found a strong correlation between the research and development (R&D) domain and the high-tech sectors.

Frankort's paper (2016) is centered on describing the knowledge achieved through to R&D alliances. In addition, he analyses the R&D alliances that offer the possibility for firms to apply their acquired technological knowledge for the development of new products. The author emphasizes on the fact that the development benefits of the new product will increase if the actors of the partnership activate on similar technological sectors and will decrease if they are active on similar product markets. Likewise, Frankort (2016) quotes Hagedoorn (1993) who thinks that the research and development alliances are official agreements that allow the firms to conduct common research and development activities with the help of new technologies, products and processes on the market. In their paper, Mowery et al (1996) examine the inter-firm transfer of knowledge in a strategic alliance. According

to Jagersma (2005) the exchange of technology remains a major objective for many strategic collaboration agreements. It is well known that technological innovations are rather rare among firms that hold limited resources; therefore these companies will opt to resort to other market actors in order to increase the life cycle of their products and the survival of the firm on the market, by fulfilling the innovative and competitive objectives. Besides the numerous advantages listed above, strategic alliances also involve disadvantages that could further expose the firm to risks. Thus, Grant and Baden-Fuller (2004) consider the strategic alliances to have a significant disadvantage regarding the "risk of competitive collaboration". In this case, the actual intentions of the companies involved in the alliance are being hidden. Thereby, there is a risk that a partner could try to use the entire alliance with the purpose to achieve an advantage over the other partners. According to economists Camino and Trecu (1996), a strategic alliance is "an emerging form of international business organization (...), a species of joint venture in which an innovation of technology contracts with another firm for the joint exploitation of technology and other assets across a number of national territories". Strategic alliances remain complex collaboration agreements established between partners with multiple characteristics that can create R&D alliances (Li et al 2008), joint ventures (Inkpen and Currall, 2004), international alliances (Oxley and Sampson, 2004) as well as other forms or organization.

According to Albers et al (2016) there are three criteria on which different types of strategic alliances are being set: activity-domain-based (this criteria focuses on the different tasks that partners are specialized on and that they carry out in the alliance <<R&D, marketing, production, sales>>); partner-characteristics-based (it focuses on the characteristics of the firms involved in the alliance or on the relevant position within the value chain of their industry), alliance-structure-based (it focuses on the way that relations between partners are being organized and managed).

Methodology

The aim of the quantitative instrument $V_{i;n}$ is to calculate the expected revenues resulted from the development of new products within strategic alliances. Thus, $V_{i;n}$ can be applied to the alliances/collaboration, cooperation or partnership agreements created by three firms that unite their strengths in order to develop new products on the market. The partners should adopt the same pricing strategy for each product "i" on the market. Due to this fact, by calculating the expected revenue, we can find out the product quantities that belong to each company after the investments allocation.

I consider the quantitative instrument ($V_{i;n}$) to be a method for calculating the expected revenue that every company receives within a strategic alliance/collaboration or cooperation agreement /partnership agreement. $V_{i;n}$ is based on the total costs allocated by company "n" for product "i" after calculating the adjustment of the initial costs and the new value of the return on sales ($ROS_{i;n}$). The companies need to start by calculating the total costs that one firm needs to allocate in order to develop the group of products 1...n, and the costs allocated by all the companies together in order to develop a product "i" from the group of products 1...n.

With the help of this instrument, we can determine the equitable profit ($\pi_{i;n}$) for the companies within the alliance. In other words, based on the method for calculating the new value of ROS, the partners will have the opportunity to calculate their expected revenues. Moreover, the firms will have the possibility to calculate the profit that is assigned to them.

As known, the ROS formula represents the ratio between a firm's profit and its revenue. By processing the formula, I have extracted the firm's revenue depending on ROS (1).

$$ROS = \frac{Profit}{Revenue} = \frac{Total\ Revenue - Total\ Cost}{Total\ Cost} = \frac{p*Q - [Fixed\ Cost + Q*Variable\ Cost]}{p*Q} =>$$

$$=> p*Q = \frac{Total\ Cost}{1 - ROS} = V, \text{ where} \quad (1)$$

p = price;

Q= quantity;
ROS = return on sales;
V = revenue.
By processing the general ROS formula, I will consider $V_{i;n}$ to be the ratio between the total costs allocated by company "n" for product "i" after calculating the adjustment of initial costs and the new value $ROS_{i;n}$ that is assigned to every company "n" for a product "i".

$$V_{i;n} = P_{i;n} * Q_{i;n} = \frac{Ct_{i;n}}{1 - ROS_{i;n}}, \text{ where} \quad (2)$$

i = product; n = company;
$V_{i;n}$= expected revenues resulted from the development of new products within strategic alliances;
$Ct_{i;n}$= total costs allocated by company "n" for product "i" after calculating the adjustment of initial costs.

$$Ct_{i;n} = (C_{i;n} - difN_{i;n})) * P\%_{i;n}, \text{ where} \quad (3)$$

$C_{i;n}$ = initial cost of company "n" for product "i" calculated depending on the total cost of product "i";
$P\%_{i;n}$ = initial indicative percentage negotiated by the partner firms.

$$difN_{i;n} = (\sum C_{i;n} - C_{f_p}) * P\%_{i;n} \text{ with two cases described below:} \quad (4)$$

I) If $\sum C_{i;k} - C_{f_p} > 0$ and $\sum C_{i;l} - C_{f_p} > 0$ and $\sum C_{i;m} - C_{f_p} < 0$ then we will calculate the following:
$difN_{i;k} + difN_{i;l} = - difN_{i;m}$ where k, l, m = companies; i = product;
II) If $\sum C_{i;k} - C_{f_p} < 0$ and $\sum C_{i;l} - C_{f_p} < 0$ and $\sum C_{i;m} - C_{f_p} > 0$ then we will calculate the following:
$-(difN_{i;k} + difN_{i;l}) = difN_{i;m}$ where "k"," l", "m" - companies;"i" - product;
C_{f_p}= the mandatory cost set according to the negotiation;
$difN_{i;n}$ =the total surplus/deficit per company;
$ROS_{i;n}$ = the new value of the return on sales for each company;

$$ROS_{i;n} = Pc_{i;n} * Pp_{i;n}, \text{ where} \quad (5)$$

$Pc_{i;n}$= the percentage that is calculated depending on $Ct_{i;n}$; it represents the cost percentage of company "n" depending on its total costs;
$Pp_{i;n}$ = the percentage that is calculated depending on $Ct_{i;n}$; it represents the cost percentage of company "n" depending on the total costs of product "i";

$$Pp_{i;n} = \frac{Ct_{i;n}}{Cp_i} = \frac{(C_{i;n} - difN_{i;n}) * P\%_{i;n}}{Cp_i}, \text{ where} \quad (6)$$

Cp_i = the total cost of product "i";

$$Pc_{i;n} = \frac{\sum_n^1 \frac{(C_{i;n} - difN_{i;n}) * P\%_{i;n} * 100}{Cf_p}}{\sum n}, \text{ where} \quad (7)$$

$\sum n$= the number of companies within the strategic alliance/agreement/collaboration/cooperation.
Replacing inside formula (2), the formulas (3), (5), (6), (7) we obtain the detailed version of formula $V_{i;n}$ (7):

$$V_{i;n} = \frac{Ct_{i;n}}{1 - ROS_{i;n}} = \frac{(C_{i;n} - difN_{i;n}) * P\%_{i;n}}{1 - Pc_{i;n} * Pp_{i;n}} = \frac{(C_{i;n} - difN_{i;n}) * P\%_{i;n}}{1 - \frac{(C_{i;n} - difN_{i;n}) * P\%_{i;n} * 100}{Cp_i} * \frac{\sum_n^1 \frac{(C_{i;n} - difN_{i;n}) * P\%_{i;n} * 100}{Cf_p}}{n}} \quad (7)$$

Simulation

For the simulation, I chose three companies that wanted to develop three products on the market. The input values of the simulation are randomly given. Accordingly, company X, Y, Z team up (pooling resources, sharing know-how) in order to create a strategic alliance/collaboration/cooperation/partnership agreement for the development of three products A, B,

C that require the following total costs: product A – Euro 1,200,000, product B – Euro 800,000, product C – Euro 400,000. Thus, the total cost of the group of products is Euro 2,400,000. The firms had assumed the costs for the development of the products. Each company will comply with the initial indicative percentage negotiated by the partner firms in order to calculate the new value of $ROS_{i;n}$. As mentioned above, the companies will comply with the same mandatory cost established within the negotiation in order to develop products A, B, C. In the analyzed case, we consider C_{f_p} = Euro 800,000. Thus, the values of $P\%_{i;n}$ are presented in Table 1:

Table 1. The initial indicative percentage established throughout the negotiation

i	$P\%_{i;x}$	$P\%_{i;y}$	$P\%_{i;z}$	Cp_i
A	50%	30%	20%	1,200,000
B	30%	60%	10%	800,000
C	20%	10%	70%	400,000

Source: Made by the author

First, we will calculate the costs of the products $C_{i;n}$ for each company X, Y, Z (Table 2):

Table 2. Product costs for each company

i	$P\%_{i;x}$	$C_{i;x}$	$P\%_{i;y}$	$C_{i;y}$	$P\%_{i;z}$	$C_{i;z}$
A	50%	600,000	30%	360,000	20%	240,000
B	30%	240,000	60%	480,000	10%	80,000
C	20%	80,000	10%	40,000	70%	280,000

*It can be noticed that C_{f_p} = Euro 800,000 is not respected.

Source: Made by the author

Adding up the values on each $C_{i;n}$ column, I have achieved the results in Table 3:

Table 3 – Total product costs for each company

$\sum C_{A,B,C;x}$	$\sum C_{A,B,C;y}$	$\sum C_{A,B,C;z}$
920,000*	360,000*	240,000*

* It can be noticed that the total cost is maintained and its value is Euro 2,400,000

Source: Made by the author

Further, I have calculated $difN_{i;n}$ (the total surplus/deficit per company) using the formula ($\sum C_{i;n}$ - C_{f_p}) * $P\%_{i;n}$. The results achieved in the analyzed case shows the fact that there is a surplus recorded by companies X and Y, and company Z records a deficit of Euro 200,000.

Table 4. Total surplus/deficit per company

	X	Y	Z
$\sum C_{i;n}$	920,000	880,000	600,000
C_{f_p}	800,000	800,000	800,000
$difN_{i;n}$	(+)120,000	(+)80,000	(-)200,000

Source: Made by the author

The differences obtained for each product per company will be allocated according to $P\%_{i;n}$. The new allocation can be observed in Table 5. For company "Z" we will apply case II: $-(difN_{i;k} + difN_{i;l}) = difN_{i;m}$.

Table 5. The new allocation $difX_{i;n}$, $difY_{i;n}$, $difZ_{i;n}$

	$difX_{i;n} = (\sum C_{i;n} - C_{f_p}) * P\%_{i;n}$	$difY_{i;n} = (\sum C_{i;n} - C_{f_p}) * P\%_{i;n}$	$difZ_{i;n} = -(difX_{i;n} + difY_{i;n})$
$difX_{i;n}$	+ 60,000	+ 24,000	-84,000
$difX_{i;n}$	+ 36,000	+ 48,000	-84,000
$difX_{i;n}$	+ 24,000	+ 8,000	-32,000
$\sum difN_{i;n}$	+120,000	+80,000	-200,000

Source: Made by the author

The values of Table 5 will be subtracted from the values of Table 2; the new results are found in Table 6:

Table 6. Total costs allocated by the company after the adjustment

	$Ct_{i;n}$	$Ct_{i;n}$	$Ct_{i;n}$	Cp_i
A	540,000	336,000	324,000	1,200,000
B	204,000	432,000	164,000	800,000
C	56,000	32,000	312,000	400,000
C_{f_p}	800,000	800,000	800,000	2,400,000

Source: Made by the author

The cost percentages of company "n" depending on its total costs and the cost percentages of company "n" depending on the total costs of product "i" are different as it shows in Table 7:

Table 7. $Pc_{i;n}$ and $Pp_{i;n}$

i	X		Y		Z		(%)
	$Pc_{i;x}$	$Pp_{i;x}$	$Pc_{i;y}$	$Pp_{i;y}$	$Pc_{i;z}$	$Pp_{i;z}$	
A	68%		42%		41%		
		45%		28%		27%	100%
B*	26%		54%		21%		
		26%		54%		21%	100%
C	7%		4%		39%		
		14%		8%		78%	100%
(%)	100%		100%		100%		

*We obtained the same percentages for product B because the Cp_i values are equal to C_{f_p} values.

Source: Made by the author

After calculating the arithmetical average of the percentages of product "i", I have obtained: $Pc_{A;n}$ =50,3%, $Pc_{B;n}$ =33,7% and $Pc_{C;n}$ =16,7%. Therefore, the new ROS values are detailed in the table below (Table 8):

Table 8. The new ROS values

i	$ROS_{i;x}$	$ROS_{i;y}$	$ROS_{i;z}$
A	0.226	0.140	0.136
B	0.087	0.182	0.070
C	0.023	0.013	0.130

Source: Made by the author

Thus, in order to achieve an equitable allocation, the companies will use the same selling price for each product "i" therefore ($P_{A;X}= P_A;_Y=P_{A;z}$ and $Q_{A;X} \neq Q_{A;Y} \neq Q_{A;Z}$):

Table 8. The expected revenues resulted from the development of products A, B, C

i	$V_{i;x}$	$V_{i;y}$	$V_{i;z}$	$V_{i;n}$
A	697,674.42	390,697.67	375,000	1,463,372.09
B	223,439.21	528,117.36	176,344.09	927,900.66
C	57,318.32	32,421.48	358,620.69	448,360.49
	978,431.95	951,236.51	909,964.78	

Source: Made by the author

Table 9 reflects the equitable profit for each company.

Table 9. The values of the equitable profit $\pi_{i;n}$ for the companies X, Y, Z

i	$\pi_{i;x}$	$\pi_{i;y}$	$\pi_{i;z}$
A	157,674.42	54,697.67	51,000.00
B	19,439.21	96,117.36	12,344.09
C	1,318.32	421.48	46,620.69
	178,431.95	151,236.51	109,964.78

Source: Made by the author

For a total investment of Euro 2,400,000, the firms obtain a total profit of Euro 439,633.24, representing 18% of the total initial costs. The profit for each firm is differently scattered, so for firm X the equitable profit records Euro 178,431.95 Euro, firm Y the equitable profit records Euro 151,236.51, firm Z the equitable profit records Euro 109,964.78. To conclude, the simulation reveals the fact that if a company invests in a product with higher costs, it will get higher profits than the other partners within the strategic alliance.

Conclusion

As known, a successful collaboration may generate great profits compared to the case in which the firm would operate on its own on the market alongside its other direct competitors. Therefore, it is important for the firm to keep its openness to a future collaboration or cooperation with its main rivals in order to develop new products.

As mentioned above, the paper keeps in attention the use of a quantitative instrument $V_{i,n}$, which helps calculate the expected revenues resulted from the development of new products within strategic alliances. One of the constraints of this research is that the instrument can be applied only for a few range of firms, namely three of them within alliances/collaboration, cooperation or partnership agreements. In order for the effect described in the paper to take place, the partners should adopt the same pricing strategy for each product "i" on the market; only the product quantities will depend on the new ROS value. Due to this fact, by calculating the expected revenues, the firms can find out the product quantities that belong to each of them after the investments allocation.

As highlighted above, the detailed simulation reveals the fact that if a company invests in a product with higher costs, it will get higher profits than the other partners within the strategic alliance.

In business, the constant need for innovation and the tendency for research and development ensure the economic growth for a company on the market. Pooling resources, sharing know-how and maintaining the desire for achieving the established goals, can be considered factors for founding new agreements with a suitable partner in order to rein the competition and extend the life cycle of the firm. By having a partner on their side, firms can become more confident about their actions on the market. In my opinion, even if the openness towards a partner might be interpreted as a risky exposure for a firm on the market, this may represent a step forward regarding awareness. In addition, the risky exposure can be rooted out by vigorous terms stipulated in the contract agreement.

In conclusion, the firm's constant flow of motivation and the acceptance of the idea of collaborating with another firm enable it to achieve its desired objectives, surpass its condition as an individual entity on the market and reach high performance by achieving a leading position on the market and obtaining the proposed amount of sales.

Abstract

This paper is dedicated to the research of subsequent evaluation of goodwill and is mainly aimed at a comparative analysis of 'amortization approach' and 'impairment-only approach'. Under a lot of criticism concerning goodwill amortization, in 2004 in IFRS the approach of 'goodwill amortization' was replaced by 'impairment–only' approach. In spite of the validity of the 'impairment testing' approach to the subsequent accounting for goodwill, which is based on the essence of treatment of 'goodwill', the application of this method in practice by companies has revealed a number of significant drawbacks. The return to the 'amortization approach' can make the financial reports more transparent and eliminate 'subjective factor'. At the same time, 'impairment of goodwill' approach enables companies to reflect the specific features of their activities and the effect from business combination. The research was carried out to estimate the impact of chosen method subsequent accounting for goodwill (impairment or amortization) through the analysis of sample of companies located in different countries. Besides, it presents 'pros and cons' these methods.

Keywords*:* accounting for goodwill, impairment, amortization, consolidation financial statements

Introduction

Such specific element of the consolidated financial statements as goodwill has been causing a lot of discussion. In particular, there is an ambiguity of opinions in regard to measurement of goodwill after initial recognition. Thereby, this paper focuses on reviewing of the most controversial aspects in regard to subsequent measurement of goodwill both from theoretical and the practical point of view. There are two main approaches to the subsequent measurement of goodwill: amortization approach and impairment-only approach. These methods also may be used simultaneously.

Under a lot of criticism concerning goodwill amortization this requirement was replaced by 'annual impairment test for goodwill' as part of the cash – generated unit in 2004 in the international standards. The main arguments against goodwill amortization were that it cannot determine the useful life correctly and is in non-compliance to the nature of goodwill.

In spite of the theoretical assertion that the 'impairment testing' approach to the subsequent accounting for goodwill is based on the essence of treatment of 'goodwill', the applying of this method in practice has revealed a number of significant drawbacks. Some companies don't calculate impairment of goodwill according to the requirements of standards or some of them don't disclose information about the assumptions in the measuring of the recoverable amount of the cash-generating units made by managers and about the allocating goodwill to those units. As a result, the information presented in the financial statements has become less transparent and comparable between the companies. It is also because the subjectivity of 'impairment approach' significantly higher than 'amortization approach'.

The research was carried out to estimate the impact of chosen methods subsequent accounting for goodwill (impairment or amortization) through the analysis of such large and long-time operating companies as: Vodafone Group (UK, since 1983), Bosch Group (Germany, since 1886), Philips

Group (Netherlands, since 1891), Nestle Group (Switzerland, since 1866), Sberbank Group (Russia, since 1991), VTB Group (Russia, since 1990). This study was conducted in order to identify the main trends of calculating impairment losses of goodwill and disclosing the information about it in the financial statements. Besides, the research was carried out to assess the possible influence of returning to amortization on the main company performance indicators.

On one hand, the return to the 'amortization approach' will help to make the financial report more transparent and eliminate 'subjective factor', which creates the conditions for veiling in the financial statements. On the other hands, 'impairment of goodwill' approach enables companies to reflect the specific features of their activities and the effect from business combination. In addition, in conditions of preparing financial statements without 'predetermination' of profit results set by managers or company's owners, the 'impairment of goodwill' approach will provide more accurate results than applying of 'amortization method'.

Historical background

The history of legal and professional regulation has a fundamental impact on the accounting methods and principles accepted today, even at the international level. International standards are unusual because they combine the features of the accounting culture and auditing practices of different countries contributing to their emergence. For more details on the impact of each parts of culture see in a research study by Zeff (2007). About the history of development of accounting theory in Russia in XX century see in the book by Mattessich et al (2008, Chapter 15, p. 246-264). The practical application of IFRS in Russia in 90s XX – the early XXI is revealed in a research study by Genaralova et al (2015) and in a research study by Kovalev (2014). In addition, the spread of the accounting profession and improving of education system influence on national and international accounting significantly (see more details in the paper by Chen (2008). The specifics of the development of Russian accounting education are disclosed in a research study by Karelskaia and Zuga (2014, p. 269). The process of formation of professional societies in Russia is described in the paper by Sokolov V. (2015). Moreover, as it is was shown throughout the history, 'pioneers' or initiators have a special influence on the development of international regulators and regulations. Thus, the development of conceptual ideas and accounting in accordance with IFRS has been influenced by the legislative requirements of the countries whose representatives took an active part in the creation of the international standards.

In 1978 the topic of business combinations was placed on the agenda for consideration by IASC with some apprehension due to the understanding that this is a very controversial issue. At that time, amortization was used as a subsequent measurement of goodwill according to national standards of majority of the countries and Fourth EC Directive. The difference was only in the duration of the useful life: according to APB Opinion № 17 (US GAAP) it was 40 years; and in according to Fourth EC Directive it was 5 years. In 1983 IAS 22 "Business combination" has been approved. So, amortization over 5 years was established as a subsequent measurement of goodwill to bring into conformity with existing practice and requirements of Fourth EC Directive (Zeff, book 2007, p. 137). However, despite the approval of IAS 22, the subsequent accounting for goodwill had remained one of the issues that have no absolute decision.

Also, according to quantitative and qualitative analysis of more than two hundred Russian and foreign scientific papers about accounting for goodwill and published from 1990 to early 2000s, it was found that the most controversial of all issues in relation to accounting for goodwill is its measurement after initial recognition (Generalova, Popova, p. 53-60).

And as a result of intense debate in the West, since 2001 according to US GAAP the 'impairment approach' has been used instead of amortization (SFAS 142 "Goodwill and other Intangible Assets" и SFAS 141 "Business Combination"). The reason for the abandonment of amortization was the following arguments. Firstly, the majority of analysts when making decisions for investments ignored the value of amortization of goodwill in the process of calculating the relevant operational performance. This was done to eliminate the influence on the fluctuation of the profit the factor of

transition from date of implementing of goodwill amortization to date of cessation of amortization. Secondly, appropriate testing for impairment with qualitative disclosure would facilitate financial reporting transparency (Fabi and others, 2014, p. 11). So, in IFRS in 2004 there was a transition to the model of 'impairment' of goodwill and refusal the 'amortization approach'. Including, this was carried out in accordance with the idea of convergence of US GAAP and IFRS.

But despite the "consent of the majority" to make the transition to 'impairment model', rear-view has emerged by nowadays due to the existence of the negative aspects associated with the procedure of impairment of goodwill in practice. Rear-view consists in the following opinion: "Perhaps, the return to amortization is a necessary measure to overcome the existing practical problems associated with the implementation of 'impairment approach' to subsequent measurement of goodwill". It is also worth noting, that the problems of accounting for goodwill arisen in practice should be considered combined with the difficulties of consolidation procedures, such as issues of perimeter of consolidation (for more details, see Crişan P. & others, 2012).

Amortization versus impairment of goodwill: pros and cons

The difficulties of implementing the impairment model in practice

After IFRS 3 "Business combination" had been released in 2008, IASB reviewed the results and consequences of the application of new the standard (PIR – Post-implementation review). It has been called into question: "Whether testing goodwill for impairment able to reflect the entity's exposure to adverse economic cycles? Besides, it was also caused concern about the subjectivity of information generated by the impairment of goodwill (PIR, 2015, p. 12).

Thus, the transition solely on impairment approach entailed existence of misinformation of users: in the presence of obvious signs pointing to the need to recognize losses in accordance with IFRS (IAS) 36, companies don't tend to show them in the statements. Besides, the problem is that losses from the impairment of goodwill are reported too late, i.e. out of time. Especially this "delay recognition of losses" is noticeable at the time of economic crisis (Fabi et al, 2014).

The next weak side of impairment approach marked by Russian authors is undergoes to value judgments (Generalova, Sokolova, 2014). Firstly, The exposure of impairment procedures to value judgments arises from specificity of the impairment model contained in the standard: 1) the allocation of goodwill to the strong or weak CGU; 2) the determination of the date for impairment procedures; 3) the use of the most recent detailed calculation made in a preceding period of the recoverable amount of a cash-generating unit to which goodwill has been allocated for the current period (see p. 99 IAS 36); 4) dependence on the choice of valuation of non-controlling interest (see p. C4 IAS 36). Secondly, there are uncertainties arising directly from the impairment model: 1) calculation of forecast cash flows is subjective; 2) determination of the discount rate (increase/decrease by an insignificant amount of the discount rate may lead to recognition/non-recognition of impairment losses).

Sokolov J. in the work "Accounting and economic crisis" outlined: "An economic crisis arises due to errors by people who responsible for making economic decision. In its turn, these mistakes are the result of an inadequate data presented in the financial statements for the subjective and objective reasons. First of all, subjective errors relate to the unfounded hopes, which are embodied in the asset valuation". (Sokolov, 2009, p. 18). Goodwill is an asset, too.

Decision ways

There are at least two solutions: the first is improving the impairment model, the second is return amortization. Standards' developers follow to the first variant. According to such opinion it is need to minimize the cost of implementation of impairment procedures. (PIR, 2015, p.16). Members of the

professional community, representatives of professional organizations and scholars have an opposite opinion

Arguments in favor of return to the amortization

The first argument: "Amortization of goodwill reflect the consumption of economic resources obtained in a business combination over the time" (Fabi and others, 2014).

The second argument is a "larger" degree of reliability of the information provided, because there is no need to disclose the numerous and ambiguous parameters for calculating replacement value of CGU to which goodwill is allocated according to impairment model. Is needed only the initial cost and useful life.

The third argument follows from the second: The ease of measurement is the key to the comparability and the verifiability of reporting data of companies worldwide.

The practice: research of the effect of implementation of the 'amortization approach' and the 'impairment approach' of goodwill on companies' financial statements

To study the effect of possible transition from impairment (the requirement of IFRS) to amortization of goodwill, we have carried out the research. The base of the research is the consolidated financial statements of the large companies operating stably for a long time in its industry. Data on the value of goodwill and data on the amount of costs related to goodwill (amortization or impairment losses) were calculated and compared. Besides, the research reveals the impact on net profit margin, return on equity (ROE) and return on assets (ROA).

The analysis of the large and long-time operating companies only doesn't provide enough representative results. But this study is intended to outline the main trends and the impact of 'amortization approach' and 'impairment-only approach'. In this paper this influence is showed in detail only at the example of companies. These companies are Vodafone Group (United Kingdom, mobile communication services, operates since 1983); Bosch Group (Germany, Electronics & Engineering, since 1886); Nestle Strategische Allianz (Switzerland, food products, since 1866); Philips Group (Netherlands, appliances, since 1891); Sberbank Group (Russia, banking, since 1991); VTB Group (Россия, banking, since 1990).

Analyzed period is from 2000 to 2014. The period for which the data were recalculated is from 2005 (2006) to 2014. The sample consisted of 62 statistical observations.

Briefly, in example of two companies show the main trends observed in the recognition of goodwill impairment in the statements.

Trends

As an example we take the Bosch Group and consider the changing the "cost behavior" associated with goodwill. Drawing attention to the columns 6 and 7 of Table 1 it can be noted that the transition from the amortization (according to the German Commercial Code – Handelsgetzbuch; 10 years of useful life according to accounting policy) of goodwill to its impairment (since 2005), impairment losses recognized every two years steadily. 2009 was unprofitable for the Bosch Group. In 2011, as in 2013, there was a decline of basic indicators of the Group's activities (profitability, revenues, total balance sheet, and profit).
It is also important to note that at drawing up of consolidated financial statements in accordance with German Commercial Code, the share of costs related to goodwill in the Bosch Group's operating

expenses were higher than in the transition to impairment in 2005 in connection with the transition to IFRS.

Table 1. Acquired goodwill of Bosch Group and its subsequent measurement: amortization and the impairment amounts, 2000-2014, million euros

Year	Goodwill at the beginning *(initial value)*	Good-will at the begin-ning *(book value)*	Increase		Decrease		Accumulated amortization / impairment at the end	Disposal	Goodwill at the end
			Arrivals	Other	Amortization	Impairment			
1	*2*	*3*	*4*	*5*	*6*	*7*	*8*	*9*	*10*

Source: Bosch Group Consolidated Financial Statements for 2000-2014.

Example of Swiss companies – Nestle Group. Transition to IFRS by Nestle Group (from national standards) took place in 2003. Hence, the use of the goodwill impairment model began in 2005. Before this transition, goodwill was subjected to an amortization and the impairment testing. Fig. 1 shows how a saltatory change in the net profit of the Group "combined with" the trends of the recognition of impairment losses for goodwill of subsidiaries. The trends are as follows: impairment losses of goodwill (since 2005) were recognized mainly in the highly profitable years for the Group.

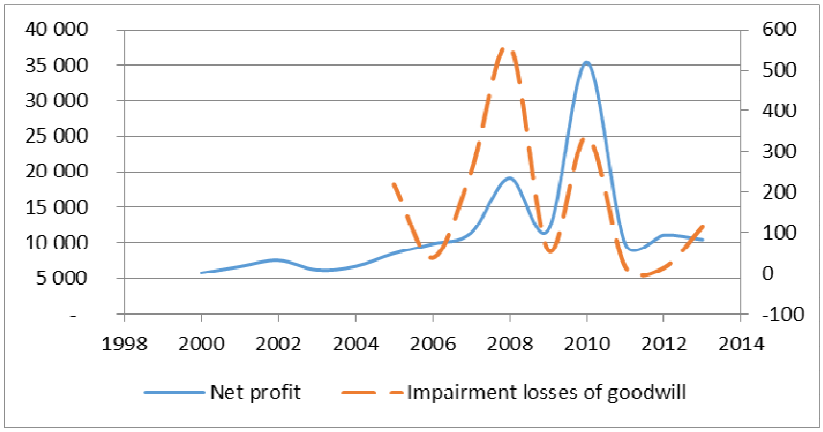

Figure 1. Comparison of the net profit and the amount of goodwill impairment losses, 2005 - 2013
Source: Consolidated Financial Statements Nestle Group for 2000-2014
(*The impairment of goodwill is based on secondary axis).*

The effects of a possible transition to the amortization of goodwill on the profitability

Table 2 shows the results of the correlation analysis of the data before and after recalculation of net profit margin (NPM), return on equity (ROE) and return on assets (ROA), since 2005 to 2013. The correlation coefficients have been calculated according to data obtained from the analyze of the sample. The sample consists of financial data for the period from 2005 to 2013 obtained from financial statements of the companies observed. Then these factual data have been restated for the same periods of time according to assumption that goodwill has been amortized during the 10 years.

Table 2. Correlation coefficient data of profitability and impairment of goodwill amortization of 10 years, based on a sample of companies, 2005-2013.

	Net Profit Margin	**Return on equity (ROE)**	**Return on assets (ROA)**
Correlation coefficient *(foe the whole period)*	**0,847566294**	**0,954148847**	**0,928573282**
2013	0,807688299	0,949775209	0,923641437
2012	0,811788862	0,951750241	0,926979954
2011	0,813927119	0,951724933	0,927481519
2010	0,814831605	0,952012296	0,928540426
2009	0,823543738	0,956176110	0,931045581
2008	0,824064223	0,956438302	0,931613558
2007	0,839090352	0,958525705	0,935430791
2006	0,840668704	0,958885067	0,937158280
2005	0,992062268	0,977914859	0,984784298

Based on the results of calculations, it can be seen that the values of profitability before recalculation (impairment; the actual reporting data) and after recalculation (amortization during 10 years useful life) have a low degree of deviation and correlation coefficient is positive and high (coef: 0,8 - 0,9). Consequently, the returning to amortization of goodwill during 10 years will not be substantially worsened for status of companies. Similar conclusion would be clearer if we look at the example of two of the companies in more detail. In Table 3 disclosed the calculated amounts of NPM, ROA and ROE for factual and recalculated data of the British Vodafone Group with deviation of these indicators (see columns 13-15). In Table 4 disclosed the calculated amounts of NPM, ROA and ROE for factual and recalculated data of the Russian Sberbank Group with deviation of these indicators (see columns 13-15).

2006	2 644	**0**	**26%**	**31%**	**4%**		2 64

Fig. 2 shows the data on which it is possible to judge at what rate to a greater extent will be affected by the transition to the amortization of goodwill.

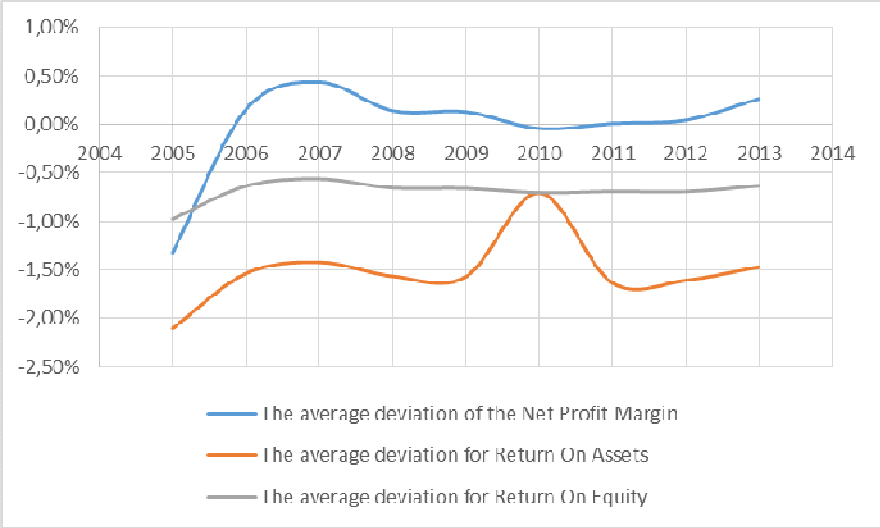

Figure 2. The dynamics of an average deviation of NPM, ROA, ROE in applying the goodwill impairment from values of the implementation of amortization during 10 years, 2005-2013

Table 5. Data on the average deviation of the profitability when an impairment of goodwill and amortization of 10 years, based on a sample of companies, 2005-2013

	Net Profit Margin	Return on equity (ROE)	Return on assets (ROA)
The average deviation	**0,10%**	**-1,28%**	**-0,53%**
2013	0,27%	-1,47%	-0,63%
2012	0,05%	-1,61%	-0,69%
2011	0,01%	-1,63%	-0,69%
2010	-0,04%	-0,70%	-0,70%
2009	0,13%	-1,57%	-0,66%
2008	0,14%	-1,56%	-0,65%
2007	0,44%	-1,42%	-0,56%
2006	0,16%	-1,54%	-0,63%
2005	-1,32%	-2,10%	-0,97%

So, based on this analysis the sample companies, it can be noted that a significant change in the Group's profitability indicators with the introduction of the amortization of goodwill will not happen. However, introduction of amortization instead of impairment (or along with) can contribute to leveling a series of problems, for which criticized impairment model applied today.

Conclusion

So, the question of goodwill measurement after initial recognition has remained one of the most controversial and unresolved issue in accounting. After refusal of the ‘amortization’ in favor to ‘impairment approach’ to goodwill subsequent measurement in IFRS, it found out that it

demonstrated a number of disadvantages arising from uncertainties of impairment procedure. This paper considers the advantages and disadvantages of amortization and impairment of goodwill.

The positive aspects of the applying of impairment as a subsequent measurement of goodwill consist of some opinion. According to this opinion, the information on goodwill formed 'impairment approach' (if it is adequate) and the proper disclosure are able to increase the transparency of financial reporting. Moreover, the 'impairment method' corresponds to the essence of goodwill, but it is not true for the 'amortization'. However, opposite case has happened in practice. We didn't come towards such transparency as we have been aimed. Applied research has shown that the disclosure of information about some parameters of the impairment procedure is ignored by companies and the impairment losses aren't reflected in the financial statements or appear after the time of appearance of negative circumstances.

With regards to goodwill amortization we can say that this method has a number of simple advantages. And at the same time, these advantages are very important. These advantages are ability to reflect the consumption of economic benefits from the business combination, reliability of the calculations (understanding them without narrowly specialized knowledge) and simplicity. However, in the global economy it is important to take into consideration the impact on business of the new methods approved in accounting. Accordingly, the authors have made an analysis of the impact of the return to the amortization on the analytical performance of companies' activity in several countries. So, with possible approving of requirement to amortize of goodwill it will be observed the decline of corporate profits. However, this reduction will not have a material impact on the change in the profitability ratios. Consequently, the "disastrous" influence on the attitude of the financial statements' users (particularly, owners) to companies will not be rendered.

In conclusion, it should be noted that in Accounting as a social science, the agreement between countries (or within one country) is more important factor than the perfection of created methods of accounting.

Abstract

This paper highlights the tensions developed during evolutionary movements had towards creating improved corporate strategy. The main pillar nuanced in this paper is functional strategic excellence that is resulted from applying the process of reverse engineering into strategic planning.

The research underlines the need for a new approach on implementation, resource allocation, due diligence and strategic planning in order to activate the best suitable solution in any environment, so at the end of the day or business cycle, the company should go forward and obtain sustainable growth that can be shifted in similar cases.

Keywords: corporate strategy, reverse engineering, strategic planning, sustainable growth

Introduction

To implement a working model to built to turn ideas outlined corporate strategy should be evaluated as factors that influence the market, but also based on uncertainty which is working and growing in the global economy and expectations taken from environmental regulations and strategic changes are required these days.

Corporate strategy requires the implementation of traced general directions. This can be achieved by the implementation of these four actuators (Day, 1987):

1. *Identify overall strategic objectives:* what are their expected results depending on the implemented strategy.
2. *Outlining specific plans:* objectives segmentation created for specific tasks are assigned on a certain period and with completion deadlines.
3. *Resource allocation and delimitation of financial needs:* it creates mechanisms and sources of funding that takes on its entire system and each stand alone.
4. *Monitoring and control:* supervision for fulfilling its objectives, using its resources in the manner described in the budgetary component.

Implementation of corporate strategy

Implementation is needed in economic systems were shaped in the form of implementation programs combined with policy making. Full program implementation is one that is based on the implementation of fundamental changes in strategic direction.

An antithetical element is reflected based on an incremental implementation program which is based on small changes made in short periods of time and are based on changes in the followed strategy. The mix of the two programs was a new program called selective program implementation.

Full implementation program is used when the destination is well defined strategically or when a step towards on a new technological advance or competitive opportunity (Lynch, 2002). Implementation turns into new strategies that accelerate progress for corporations, but it is that the change processes could be painful for those taking part.

Incremental implementation program is the perfect solution for the situation of uncertainty in future for corporations or unclear located in the concept and linearity of implementation when it comes to global leaders (Lynch, 2002). This type of program is used most often when Research - Development divisions create new niches, new ways forward, but the destination is not clear, but only intuited or contoured. Traveled tasks and deadlines in this case requires flexibility or at least buffer areas (margins) for no friction or downtime. It must be added the deployment flexibility and freedom in the reconfiguration strategy with the possibility of discovering new ways of working (Day, 1987).

Selective implementation program is used when the basic solutions are no longer appropriate as response for the situation (Lynch, 2002). They can be linked to gradual therapy and shock therapy and whose mix would create a solution easier to implement and with results visible in the corporation, and also with a better yield than the implementation of government program.

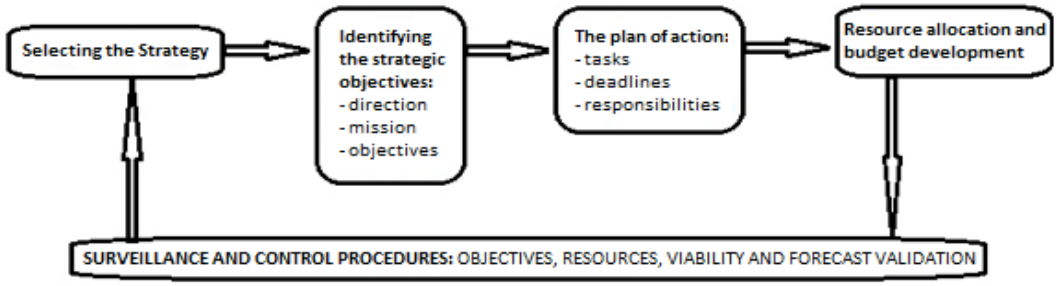

Fig 1. Pre-trial phase of implementation of corporate strategy

Source: the authors, starting from Lynch, 2002

These deployment models can be configured for application in the entire spectrum of companies, whether small, medium or large, since implementation refers to activities of developing the strategies that are found in all organizations, relying on the appointment as an overall strategy, creating specific plans and insurance funds for all should be monitored and controlled to ensure compatibility and their fulfillment.

The creation and implementation of corporate strategies is reflected in any working cell of their implementation, the individual being the undividable unit for such progress. Individuals make rational decisions, but including also personal ones during the implementation process, which may not coincide with the goals of the organization, so implementation is aimed at secondary use of systems for monitoring and control to ensure consistency for all personal goals and also for organizational ones. In order not to suppress freedom in innovation, sustainable growth goes hand in

hand with promoting success of a corporation and must intervene as a minimum lane guidance for the optimal direction (Bodislav, 2015, pp. 257-264). Perhaps that is why Hrebiniak and Joyce considered to provide a definition of the idea of "minimal intervention": *"In implementing the strategy, managers must present minimum change which is only necessary and sufficient to produce a lasting solution to a strategic problem that is addressed."* (Hrebiniak, Joyce, 1984).

The idea of implementation should be seen in the big picture, that in addition to a flexible work procedure there should be added the known facts and what should be achieved and can not be known in advance to reach concrete result of the implemented strategy. Basically the result of the strategy being outlined and adjusted like the manual focus of the lens of a camera. This idea was presented by Pettigrew and Whip (1991) and outlined three aspects to look out when it comes to strategic change:

- *Analytical aspects:* using change as a tool is made complicated when keynotes are offered by outsiders;
- *Educational aspects:* new knowledge, trends and observations to empirical information that is related to its strategy to create frameworks, keep them running at full potential and also collaborate with corporations;
- *Political issues:* observations regarding public affairs and policy issues had with created positions as streamliners between corporations and countries.

Resource allocation

The allocation of resources is an important step in implementing a successful corporate strategy. To create an efficient allocation of resources it should be established a command or responsibility center in the Operations Division under the control and supervision of the board of directors, this center has as an important role, the one to set the allocation priorities by passing through a three criteria developed filter for resource allocation:

1. *The contributions and resources required to complete the mission and target corporations as future partners:* resources are limited and they should be allocated or attracted through financial effort or relocated from other projects that are in progress, but no longer seen as a priority in the future corporate strategy;
2. *Supporting key strategies:* elaboration, implementation and execution of several key strategies must be power played and also prioritized. Implementation is based on the available budget, plus complicated position had by a new competitive advantage inserted in the market;
3. *The strategic risk had by new business proposals:* risk is inversely proportional with the institutional success rate, but it must be yield for the expected future benefits had by IT&C advance and its relation with financial investments and a certain level of risk.

The systemic importance of resource allocation is based on work principles that should take into account all internal factors and leveraged with the external factors. Hamel and Prahald (1994) consider as an ambiguous path the idea to build a corporate strategy starting from the principle of efficiently and optimal sharing structure of resources as part of the company's corporate strategy:

"If top management devotes more efforts in the feasibility of strategic projects and in its capacity to allocate resources than the multiplier effect for the idea of efficiency and the added value will be truly clear but not great." (Hamel, Prahald, 1994)

Strategic planning

To create a linear flow without having a rupture during the process requires strategic planning for the whole operation in line with the process to implement corporate strategy. Strategic planning is a formal system of planning for developing and implementing strategies for reaching and achieving the

corporate mission and objectives (Lynch, 2002). From all these we could pave the way towards a prescriptive evolutionary strategy, including also the evolutionary status that follows the entire process:

Strategic planning has three main characteristics:

- *Top-down:* the executive board has initiated an execution process and its paths for implementation;
- *Bottom-up:* the executive board engages divisions, subsidiaries, departments or even middle management to provide observations and help in strategy development and planning even if these components are complicated for those beneath them (entry level and other components);
- *Integrated:* complicated intra-corporate collaboration created through a mix between top-down and bottom-up processes.

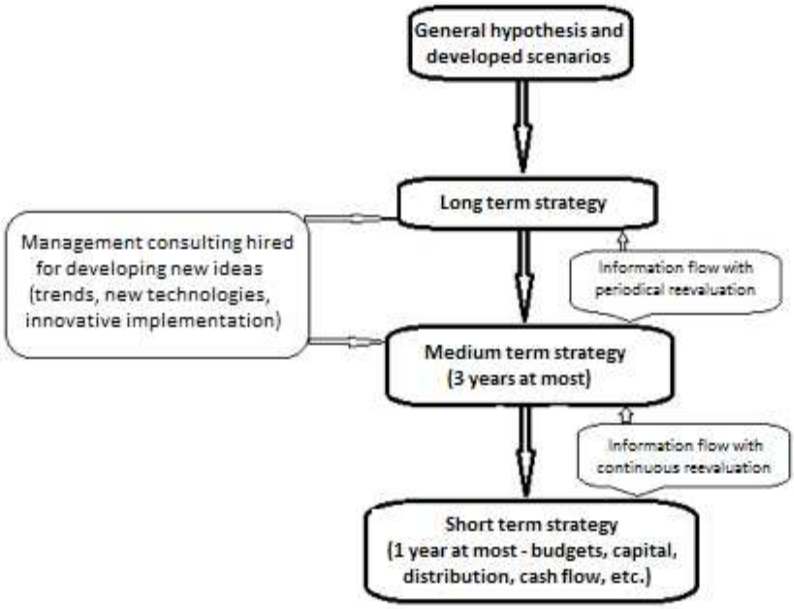

Fig 2. Reverse engineering system for strategic planning

Source: the authors

The concept of strategic planning has evolved since the 1960's, so at first the concept was seen as a way to get a higher return, idea neutralized by the oil crises of the '70s, so this concept was passed in the background, except Royal Dutch Shell who saw it as an opportunity to create long-term development scenarios, but until the '90s the concept was perceived as a rigid bureaucratic system when it came to creation and implementation (Lenz, Lyles, 1985).

Among those who noticed the bright side of strategic planning was Henry Mintzberg which has been identified as the main force for promoting the idea of strategic planning in making operational plans, him being one of the creators of the implementation phase (Mintzberg, 2008). For the idea of developing the corporation, Mintzberg has added three ways to accelerate efficiency (Mintzberg, 2008):

- Support the communication process in its entire corporate evolution because it encourages innovation and helps in having better public relations with host/partner countries;
- Helps in finding new solutions followed after by a 360 degree assessment of the local business plan;
- Providing new or alternative solutions for strategic issues.

The purpose of strategic planning is to create added value in the system. Research conducted to date suggest that the only way is to create added value by:

- *The influence had in planning:* the board defines the plans for each activity;
- *The influence had in control:* the board controls strategic planning process while the plans although complicated, are implemented.

Following the evaluation of these ways to add value to strategic planning through implementation we need to address three styles of strategic planning, all of them being based on the decision making process of the corporation (Mintzberg, 2008):

1 *Strategic planning:* the board formulates plans for each component of the corporate nexus, and during their implementation they develop control measures to reach the objectives issued in the long term strategy;
2 *Financial control:* the board controls the operations and the finance department on short and medium term, and on the medium and long term the control is transferred towards the divisions that execute (top-down transfer);
3 *Strategic control:* the board grows and strengthens the link between strategic planning and financial control through strategic control that states that the organization should have a loose streamlined hierarchical structure (a soft control developed from the center towards the subsidiaries).

A special case is the strategic implementation in the public and nonprofit sectors, because they did not mark the profit, they only serve specific functions that can not be subordinated to the private sector because they can not maintain a line of work without intersecting elements of a classic business process that involves obtaining profits (Mintzberg, 2008). To nuance the approach taken in these special situations (public and nonprofit), we developed the following framework:

Strategic planning in the public and nonprofit sectors:

1 *Bureaucratic level (public sector):*
a.Introducing the perfect targets;
b .Creating the rules (cause - effect);
c.Creating national standardized operational procedures.
2 *Clear anarchy (non-profit / charitable organizations)*
a.Undefined final target (but the ultimate goal is defined - mutual aid / philanthropy);
b .Decentralized decision-making;
c.High subjectivity needed for reaching the goal.
3 *Political power (universities):*
a.Pluralist decision-making, the targets are created by intersecting proposed targets filtered with decisional freedom;
b .Undefined coalitions, but based on specific interests, used for reaching the proposed targets of the organization;
c.Regulated decision making;
d .Neutralizing informational asymmetry.

To have a better correlation between the initial situation, the one during implementation and the resulted one there is the need for strategic control of the efficient board, and this can be achieved by:

- *Aggregating KPI* (key performance indicators);
- *Creating limits and liabilities between*: C-level suite (the executive board, the CEO and the chairman), the top management (the divisions and departments directors, for example: sales, operations, financial, marketing, etc.) and the execution division of the core-business;
- *Under sizing its importance of quantitative data:* numbers are easy to quantify, but the quality and meaning is the main differentiator in observing the yield of the strategy;
- *Control integration:* to neutralize the subjectivity of the human factor;
- *The possibility to reevaluate the situation in real time perspective and to create feasible expectations.*

Creating a unified strategy

Till this moment, in this research paper we studied the concept of corporate strategy as consisting of several elements of implementation, now it must be observed as a whole and how it functions at the level of each component.

In 1970, the consulting company Boston Consulting Group introduced the matrix product portfolio designed for children products, but the portfolio was differentiated depending on the child typology, whether they were poor, rich, troubled or famous. One of the competitors of that time (and today), McKinsey & Co. created an alternative model for organizations. "The 7S" was developed by Richard Pascale and Tony Athos (1981) and perfected by Tom Peters and Bob Waterman (1982). This model has the goal to build relationships with double meaning (feedback) within a corporation and is the best corporate strategy for implementation, underlining this way the fact that the yield of a corporate strategy is higher than using a analytical toolkit in combination with organizational structure and strategy (Lynch, 2002).

The 7S framework

The 7 components mentioned in this model are treated with the same importance in the working system of corporate strategy and they interact unconditionally to allow developing a synergistic effect on the corporate strategy of the organization. This model is designed as a bridge between corporate strategy, corporate structure and system built to bring their contribution style, skills, know-how and employee corporate goals together. The 7S model includes the following components:

1 *Strategy:* the needed component for the corporation to reach success;
2 *Structure:* the approach on doing business;
3 *Systems:* information and execution flow integrator that creates the layers and sub-layers that shape and develop the actual business (in attractiveness, market compliance and all level competitiveness);

4 *Style:* the way it implements corporate governance at executive level;
5 *Staff:* people who creates and form the corporations;
6 *Skills:* the optimal combination to assure efficiency in developing the corporation;
7 *Super-goals:* they represent the intersection between corporate goals of employees that should interact with the proposed goals of the executive board, creating together the strategic corporate vision which is adopted through applied corporate governance for a sustainable growth of the corporation.

These seven elements are divided into two groups: the hard elements: strategy, structure and systems and the soft elements: style, skill and super-goals. The difference between the two groups is the fact that the first group is based on their tangibility, but the importance is given to the soft elements group based on their character, which is more difficult to assess as planned or measured.

According to Peters and Waterman (1982) companies addressing an appropriate framework for the work of the 7S develop the premises for qualities characteristic for performing corporations, through:

- *Using loose-tight principle.* The board decides and implements the corporate governance, but not suppress entrepreneurship by providing freedom in their decision to implement at the local level or regional level (decentralization);
- *Action oriented.* If an issue rises, then it is solved on the spot with a fitted solution that is optimal for the situation;
- *Offering support and demanding feedback from clients;*
- *Innovation oriented personnel;*
- *"Simple is better!"* (Steve Jobs). This concept is also applied into the development of the organizational structure, at hierarchical level and based on the execution and liability functions;
- *Respect for human resources.* Providing opportunities for vertical and horizontal hierarchical promotion in the corporation by developing new tasks, by offering trainings and financial rewards and complementary perks;
- *Keeping the values and the mission of the corporation;*
- *Keeping the core competencies for skills.* The evolution of some business from corporations diversify the needed skills, but the basic or core ones are fundamental for any new business.

Conclusion

To implement a corporate strategy there should be evaluated and built some possible scenarios for the development of the global economy, to which we aggregate the changing of the consumer behavior and of the expected demand goods and services necessary for the long term. To project the corporate strategy some components of the global economy must be inserted in the yield equation of the long term strategy, some of those components are:

1. Globalization;
2. Global competition;
3. Super-connectivity developed by the IT&C sector;
4. The transfer under public governance of the corporate governance of some strategic companies that are state owned;
5. Environmental protection;
6. Implementation of mergers, acquisitions and alliances;
7. Ruptures in technological development and innovation;
8. Assessing an efficient demand and optimizing production facilities;
9. Consumer behavior;
10. The optimal level of decentralization.

To have no gaps or inflection points in strategic planning there should be brought into the limelight the monitoring and control components, which are executed using information from channels that are formal, informal, or internal or external. Monitoring and control are based on information available to: assess the options for allocating resources, monitoring progress in implementation, performance evaluation of top and middle management based on performed tasks and change the assessment of the economic situation and matching corporate strategy under implementation with it.

In the end of this research, we could underline the fact that the corporate strategy represents a mix of solutions that offer a company the perspective to implement, allocate its resource efficiently, develop strategic planning, reverse engineer some processes seen inside the company to fine tune them or reverse engineer some processes from competitors to develop a new process that could help grow the company that tries to reconfigure its corporate strategy.

Abstract

This paper tries to highlight the social, cultural, political and economic perspectives developed after the economic crisis started in 2007. A "new normal" was developed and it ignited the need for a new approach in the way business is done and economic policy is developed and implemented.

The main purpose of this research is to stress that today's "new normal" represents unstable trends for the global economy, reduced economic growth and unclear solutions for expected paths developed by the governments that have to develop measure for recovering after this crisis and also prepare for when the next one will come, and after all of these the secondary purpose is to highlight the way to deal with the "new normal" from the social and economic perspective.

Keywords: economic growth, economic policy, inflation, new normal

Introduction

The concept of "new normal" is defined by low economic growth and low inflation. The branch of the European Central Bank situated in Austria underlines that "the new normal is a situation where we have low economic growth, slow inflation and low profitability of banks, poor quality of assets and less short-term funding", through the ideas disseminated by Ewald Nowtony in 2014.

Economic growth is an evolution of an economy in a positive way, which may present oscillations in a limited time, and is generally presented by the evolution of gross domestic product. Economic growth is influenced by various macroeconomic indicators such as gross domestic product, gross national product, national income, coupled with demographic evolution (Ailenei, Mosora, 2011).

Economic growth means increased potential output of the economy. This means that GDP should grow to influence long-term aggregate supply and give it a positive trend. Gross domestic product is determined by the value of goods and services made by using factors of production within a country over a period of time, (generally a year).

Growth is driven by various factors, both directly and indirectly. Directly, through the active population, the amount of capital used, technological developments, and indirectly through institutions and government.

The macro-perspective of economic growth

Economic growth is closely linked to other macroeconomic issues, such as economic balance, because growth will increase imbalances in an economy without a large core formed by the middle class and institutions; cyclicality, as in the case of an upward trend in economic activity in the long term, it is known as economic growth; economic development, involving a process of change in society, which can negatively influence economic growth if the change is not favorable for the company. To have economic growth, a state must implement various measures to stimulate economic growth, which requires an accurate picture of an economy. This image or big picture is based on visible indicators and macroeconomic variables. At the same time, economic growth is influenced by macroeconomic policies (Bodislav, 2012). These policies are implemented solutions used to adjust macroeconomic imbalances and to reach economic growth. The main policies used are monetary policy and fiscal policy.

These macroeconomic policies are unfolded by the state that intervenes in the economy by changing the values of parameters and variables to find solutions to the economic problems facing the country and meet the main economic objective of the state. These solutions and objectives differ from country to country, because countries have different economies and interests. This is observed in the level of development of countries, but also in the the behavior of the population.

To achieve a positive outcome on economic problems, people need to understand those issues and take the necessary measures to solve them.

"To ensure a certain level of economic growth there are required two capabilities: either ensuring that economic growth has an extensive side (based on increasing the number of employees) or improvements in work conditions, this way allowing increased productivity (assuming such an intense economic growth – Costica, Lazarescu, 2004)". If the second aspect, to have intensive economic growth, the best solution is new investment. This can be a problem because some countries do not attract the interest of investors for several reasons, such as political stability, military, financial, and taxes.

To develop sustainable economic growth, a state must remove long-term problems. This is not always possible because the state is more interested in solving the present problems than those that have not yet occurred and no one knows when they put the state in difficulty. Long-term problems are replaced with those on short and medium term and because of the political decision, also because every governor, president or prime minister wishes to solve existing problems and those that may arise during his tenure and does not have a long-term view on the economy and also on problem solving requires which also requires a greater time of solution construction.

Neoclassical economists deemed that to have economic growth is necessary to increase production through technological improvements and also by increasing exports. Economic development in terms of neoclassical theory involves increasing savings rate and boosting technical progress, but not all countries have the same level of technical knowledge, and therefore, the least developed countries will begin a process of catching-up to try to obtain the necessary elements of technology and economic growth in developed countries that already went through these processes.

Increasing macroeconomic potential for obtaining economic growth

To show how economic growth is influenced by the accumulation of physical capital, the increase in the saving rate, population growth and technical progress, the neoclassic Solow-Swan model was developed. This model requires assumptions that there are two factors of production, labor and capital, easily substitutable, perfect mobility of factors of production, full employment of resources and the absence of state intervention. In this model, the growth rate of real GDP depends on physical capital per worker endowment. Where increases in physical capital per worker, the production increases and the economy is growing intensively, but later it will develop a new technology that will

increase capital endowment, meanwhile the production will be increasingly smaller, due to the production of goods with a higher added value and the economy will increase because of the qualitative side (Bodislav, 2015).

According to the Solow model, the higher the savings rate, the higher the growth of that economy. The International Monetary Fund recommends that developing countries have a higher savings rate and investment enters at a faster pace, these being part of the recipe on how to record higher growth.

The Solow growth model shows that government spending is not beneficial for economic growth, while an increase in taxes would stimulate this growth. If government spending increases, saving decreases, leading to a decrease in investment, but an increase of taxes, saving is stimulated, but following the drop in consumption and investment.

To have growth, developing a state there must be followed a process of evolution both in terms of technology and in terms of quantity and quality of the manufacture and products manufactured. For example, the countries of Central and Eastern Europe have followed a process of catching-up starting with the 1990's, after the exit from communism, the process was based on importing capital and technology from more developed countries (Staicu, Staicu, 2007).

A low economic growth requires a country to have growth, but it is not very visible, the growth rate of GDP is very low and maintains a low level for long periods of time. Along with low economic growth, "the new normal" implies low inflation. Inflation is a general rise in prices analyzed over a period of time and presents a macroeconomic imbalance related to monetary policy. Meanwhile, inflation is declining the purchasing power of money. At the same time, inflation is characterized by currency depreciation not only nationally, but also in relation to other currencies.

Inflation as pressure point for economic growth

Inflation is measured by macroeconomic indicators, such as the price index and consumer goods, the general price index and the GDP deflator. Inflation is caused by several factors such as demand, supply, wages and costs. Inflation in demand occurs when demand for goods and services is greater than the supply. In this situation the population experiences a desire to purchase a larger quantity of goods and services. Thus, this happens by increasing aggregate demand and as a result the prices will rise.

Inflation on the supply side stands when aggregate demand falls. In this case, the prices of goods and services will increase as on the market there will be fewer goods and services and their price will be higher.

Wage and cost inflation is achieved by starting with raising salaries that attracts and increased production costs, resulting in an increase in prices of goods and services. This increase in production costs is driven by rising commodity prices (the core being represented by materials and energy). At the same time, rising costs and imported inflation may rise, rise in prices that can be observed for countries that are dependent on the external environment, the level of imports is very high. Imported inflation is caused by rising prices worldwide that will cause a rise in prices of imported goods and services.

Along with inflation, there are two phenomena closely related to it. They are deflation and disinflation. Deflation is the opposite of inflation, namely lower prices, while disinflation is in the process of slowdown in prices (these two are seen mainly in the European Union in the second semester of 2015 and during the first quarter of 2016). A lower inflation rate further indicates that prices rise but the rate of price growth is low, close to 0. This is not always good because some countries can reach deflation.

The transition to the “new normal”

Economic growth is determined by GDP. The latter has an influence on aggregate demand and aggregate supply, but aggregate demand is the sum of market demand and it expresses total demand for goods and services in the market that they are acquired by the whole society according to the average price level in the economy known as the equilibrium price and the quantity that is traded, the equilibrium quantity. It presents various combinations of price and income for the economy in balance.

Aggregate demand can be modified by certain factors, the most important factor being price. An increase in price leads to a decrease in demand, while a drop in demand will grow the price. Other factors influencing demand are components of aggregate expenditure. For example, aggregate demand increases when consumer spending is growing, which in turn leads to an increase in consumer wealth, so it results in a price increase and on the long run in lowering taxes. This tax reduction will stimulate investment and reduce interest rates. However, export has a pretty big influence on aggregate demand, because if net exports are increasing, imports will have lower values than exports, so to stimulate national economic growth they are needed to be correlated with export earnings (Bodislav, 2012). Net exports is also influenced by the exchange rate, because if the national currency depreciates, exports will be encouraged.

Aggregate supply represents the sum of all market offerings and represents total output of goods and services that businesses from one country at an average price are given, fact achieved by the economy. For the analysis of GDP is needed long-term aggregate supply when it has the tendency to be perfectly inelastic.

If an increase is highlighted then the market supply of factors of production and demand increases, leading to an increase in input prices. Companies' profit drops to reach a neutral level and firms will no longer be stimulated to produce.

Short-term aggregate supply changes are based on amendments to certain factors, such as factor prices and inflation, which is the most important. If the supply of factors of production will fall as demand increases, the price of production factors will increase and lead to a reduction in aggregate supply.

After the last economic crisis that was felt worldwide, started in 2007, there was a time of recession, that in some view points is still in action. This recession has developed differently in the countries affected by the crisis because they used different measures to end the crisis, depending on the level of development of the country, but also on other factors such as political system and the economic system of each state.

The recession is now an output gap recession, characterized by a level of potential GDP lower than real GDP. This gap can be recovered using state or central bank intervention. State intervention can be seen by promoting countercyclical policies in fiscal policy, that is seen for example by lowering taxes during their growth during recessionary and inflationary cycles. The central bank can promote in turn an expansionary monetary policy by lowering the reserve ratio or the acquisition of securities, which will lead to an increase in the money supply, a decline in interest rates and increased investment and production of goods and services, and thus resulting in an increase in real GDP.

In the case of less developed countries, the economy had suffered much from the crisis, needing more recovery time, which led to a recession stronger and harder, but with reduced output gaps. Meanwhile, countries that promoted anti-cyclical policies, the recover was endured easier and they had less time gaps during the recession because of the population adjusted itself to the measures implemented by the state.

To understand and surpass the situation of low growth and low inflation, a country will adopt measures regulating the economy less beneficial to it, so people unable to adapt to these measures

will not stimulate the economy in the way they would want. These measures may be adopted by the government through fiscal policy or monetary policy of the central bank.

Romania and the “new normal”

During the communist period, Romania tended towards economic growth, thanks to the government that encouraged production transferred all for exports (maximum net exports) and an unemployment rate as low as possible. After 1990, Romania had a period when growth was obtained, including hyper inflation seen in the first decade after communism, all these happening until 2008, when the crisis began.

Starting with the ‘90s, in Romania there were several changes, starting with the government's objectives in relation to the economy. It started with the privatization of major industries in the country, because the state no longer had the resources to maintain and develop those businesses. Over time, the Romanian state has attracted more and more investors due to liberalization of the economy and latter on by joining the European Union.

The end of communism was followed by the process of liberalization of the Romanian economy, which began with the liberalization of prices, accelerated trade liberalization, liberalization of external flows and financial, and ended with monetary liberalization. The liberalization process was completed with the accession of Romania to the European Union in 2007.

To join the Eurozone, Romania has to meet several convergence criteria set out in the Maastricht Treaty. These criteria are divided into real convergence criteria and nominal convergence criteria.

The real convergence of living standards requires that development to reach the countries in the Eurozone. Real convergence refers to Romania's economic growth in the long term, which will help the country to adapt quickly and easily to the new currency. This convergence has strict criteria, it requires fighting unemployment, a balance of payments maintained in equilibrium, also a growing income per capita and better management of government spending.

Nominal convergence is well defined by five criteria that must be met simultaneously for a longer period, those covering monetary policy and fiscal policy. To fulfill these conditions for nominal convergence, Romania must have an inflation rate that does not exceed by more than 1.5 percentage points the average of the three countries with the best results on prices stability, the exchange rate must maintain its limits fluctuation provided by MRS II of +/-15% at least 2 years, the interest rate does not exceed by more than 2 percentage points the average of the first three countries with the lowest interest rates. From the perspective of fiscal policy, Romania must have a maximum budget deficit of 3% of GDP and public debt not exceeding 60% of GDP. The last two criteria were difficult to keep in target, the budget deficit was surpassed by almost all developed and emerging states, and the public debt criteria escaladed from 21% back in 2007 to 39% in 2015.

In the timeframe 1990-2007, Romania faced a fairly high economic growth, the crisis that followed having a greater effect on the country and pushing the country back with 5-6 years. Economic growth is influenced by many the change of factors, such as GDP, inflation, unemployment, investment, technology and other derivate or hybrid ones.

If the unemployment rate in Romania had lower rates until the crisis of 2008, starting from 2009 due to the increased depression, Romania was ranking among the European countries with the highest rates of unemployment.

Romania's gross domestic product has registered an increase up to the crisis, then it began to fall because commercial inhibitors evolved and decreased production, but over time it began to rise again and in 2013 registering the highest growth in Europe of 5,2% year on year. This growth was large, but not very big compared with the loss registered by Romania starting from 2007 and the population is still affected by the recession, only from 2015 it started to fill as a better situation for the

population.

Economic growth may be restoring confidence in the national currency, the banks started to grant more loans, investment were reignited, the production of companies increased, leading all together to GDP growth, but not all start-up companies have benefited from the economic growth after the crisis, many have reduced their lifespan on the market, entering into bankruptcy because consumption has not grown as it should or expected.

Production is stimulated by consumption, and if people lean more towards savings than for consumption, businesses will suffer, because production will decline, this decline leading to a decline in the overall economy, but in the case of emerging economies like in the case of Romania, it will result in low economic growth and a permanent muddling through process. To prevent these things to happen after the crisis and to encourage people to invest to circulate as much money they can, the state can intervene through countercyclical fiscal policy measures, by offering grants to investors, or by reducing taxes.

Investments were stimulated by lowering the monetary policy interest rate, but also by joining the EU has encouraged the state to attract FDI. With the help of investors there was completed the privatization and stimulated the economy and also brought new opportunities for development. Along with these investments, the technological advance has been ignited, especially in the manufacturing area.

For stimulating investments, the central bank may intervene by lowering monetary policy interest rates that will lead to lower reserve ratios. Through this measure the commercial banks will adjust their interest rates, encouraging people to borrow, the loans pool will increase, and with it will increase investment, thus stimulating economic growth of Romania.

Economic growth may be hampered by higher tax collection and a streamlined fiscal system used by the government, especially potent during the economic downturn. According to A. Laffer, high taxes don’t go together with paid taxes and we can state from the macroeconomic perspective that they also don’t go together with consumption and especially with aggregate demand, and this three-way procrastination resulted in a budgetary deficit becoming the country's largest. At the same time, economic growth is discouraged and high rates of government spending are seen during the recession because rather than reducing spending, they will continue to invest (in key macroeconomic areas), and thus the budget balance will be negative.

To create or maintain a high economic growth rate, the government must adopt countercyclical measures by lowering taxes and lowering government spending. Meanwhile, the central bank must also adopt policy measures that encourage lending and investment, but also to introduce liquidity, leading to an increase in inflation.

Currently, Romania is confronted with low growth rates and low inflation, but this is similar with being present in the "new normal". This is possible due to the transition which was harder than the actual recession and because of the economic stimulus measures that were adopted by the government, they were ineffective.

Conclusion

Since the economic crisis of 2007, many countries have encountered strong drops in their macroeconomic indicators, some being affected for a longer period than others. Both the countries and their central banks have long suffered due to the recession that followed, recording large deficits and a harder path to cover and recover.

Inflation began to grow during the recession, especially in the European Union it has increased slightly, but still remained at a low level, with deflationary tendencies. After the recession, the EU recorded rates of inflation that could worry its population because it was possible that a drop in prices

was ignited by the propensity of people living longer and saving less for later consumption.

In the end of the year 2014 the EU was persuaded to adopt a quantitative easing program due to very low inflation values of member countries, and some members of the Euro area recorded even deflation. This program involves the purchase of bonds and assets on the secondary market by the European Central Bank. With this decision it is stimulated a higher inflation, actually reaching a normal level and later stimulated economic growth due to the injection of liquidity in the system.

Quantitative easing is a whole process developed to create economic growth. It starts with the printing of money by the European Central Bank for bonds to be bought. Households and firms will be able to borrow due to lower interest developed by a monetary system with "cheap money". This will lead to an increase in investment and also create jobs that will help lower the unemployment rate and an increase the aggregate demand.

Following this program, countries outside the euro area and Russia could benefit. The euro area is one of the largest importers of oil in the world, and this will have a pretty big impact on the Russian economy, increasing oil imports, although the price for the oil barrel it is at its lowest point in almost two decades. With increasing inflation, also the supply (production) will increase, and it will bring economies closer to an equilibrium between potential GDP and actual GDP, the gaps getting smaller. After the crisis of 2008 the strong countries in terms of economic development have been less affected thanks to the measures taken in the pre-crisis period, while the least developed countries had a longer period of time to endure in the recession. Among the latter, some have got to have increasingly higher economic problems due to the measures used to combat the crisis and stimulate the economy that was not suitable for the system and their economy. For example, Greece, which failed to overcome the recession, nearly bankrupt, had to borrow from the IMF and the ECB, being in debt for a large period of time and owing more then 300 billion dollars to creditors.

There were also developing countries that have passed quickly over recession due to stimulus measures developed by the government for obtaining economic growth, such as Poland, one of the post-communist countries of Central and Eastern Europe.

Recession was greater in some countries and the restrictive actions of pro-cyclical fiscal policy were visible, those being also implemented in Romania. Thanks to these measures, the national economy suffered because the taxes were increased during the recession and this way having a lower aggregate demand.

If counter-cyclical measures were adopted then the recession will pass easier, the consumption being encouraged by lowering taxes. At the same time, they encourage investments that will lead to an increase in labor supply, also into a decrease in unemployment and an increase in production. The economy is growing and at the same time it is in a state of steady development. If the member countries of the European Union that were in a situation of low growth they could have adopted various measures to stimulate the economy, measures that can be used by any country, developed or developing/emerging.

Abstract

This research paper is targeted towards the globalization process in general and Romania's evolution in particular, and tries to present how the globalization process can help developing countries to reduce their gap between them and advanced economies. The main idea is that this study emphasizes also how globalization could represent an accelerated way to forget communism and embrace the open market economy also known as the capitalist system.

To understand the strong link between globalization and economic development for ex-communist countries, the paper inserts in the spotlight Romania's case and highlights the processes that accelerated the development of these countries, for example Poland's case of perfect sustainability in its evolutionary process towards it being a developed country.

Keywords: capitalism, communism, globalization, transition therapy

Introduction

Currently, globalization is increasingly seen as a process that, if managed effectively, can lead to sustainable development of the economy and society. Barriers that hinder this development are political, cultural or strategic. Political because some countries have a democratic political system different from those situated in a corrupted democratic system, which prevents factors that favor globalization. Cultural inter-penetration of Western culture represents a soft side of globalization, from where capitalist and democratic ideas and technology can evolve, where the culture of post-communist states or countries highlight globalization, but also block it with a strong nationalistic spirit developed in people's consciousness. Moreover, in such states are emerging extremist nationalist movements, especially if reforms fail to empower globalization as a tool for better living standards. Strategic barriers are also seen in wrong or hasty adoption of capitalist and democratic values and theories, especially in an institutional framework unprepared to cope with such sudden changes. Shock therapy used in some post-communist states for their transition from communism to capitalism presents exactly these problems.

Removing those barriers is a hard task, but not impossible to states that want development and deploy trades into the globalized world. Romania is one of those countries that make efforts to achieve economic development and have as political prerequisites the ideas to transform themselves as a stronger European economy and to succeed to reach a standard of living at European standards. The outbreak of the economic crisis in 2008 prevented Romania to continue the upward economic trend developed before the crisis, but there are some opportunities unfolding for Romania as a member of the European Union.

Removing barriers as forward movement for developing countries

The world is in constant change and globalization offers the transformative perspective for its citizens, but with a pace that is higher and higher. These days, globalization represents a new network formed between people, countries, institutions or organizations that are increasingly interconnected and this movement is seen only as a forward movement, but while globalization began centuries ago and reached its peak in past decades, with barriers that slow down the conversion and represent modern forms of classic thinking. Some states still reject the trend of globalization through public policy that is unfavorable for the development of free market or through corruption or lack of well-structured strategic planning at government level used to enable harmonious development of an economy in this era of perpetual transformation.

Globalization as a process is refused by certain countries that use economic, political, cultural, strategic barriers to justify their purpose. These barriers halt or slowdown the progression of the market and society, and such countries and their economies are developing unevenly. In a fictional world in which all countries have equal opportunities, resources, technology, etc., globalization would probably be accepted more easily, because all the agents involved would benefit and no one will lose.

Developed countries, developing ones and underdeveloped ones are connected by the following differences: economic, political and socio-cultural. So, for a harmonious globalization we can deduce that three ideas are mandatory: liberalization of the economy, political democratization and universal culture (Dumea, 2016).

Therefore, globalization evolves as a network, heading from developed countries towards developing countries, which offer a natural resistance that from time to time is modernized at economical level, artificially increasing the economy by imitating American or Western European model. The increase is artificial because these countries lack the same conditions as the models they aspire to reach in terms of results and, in any event, within a short time. The followed path is considered the economic side of globalization that tires to entail modernization and target the political and the socio-cultural sides. Many countries have endangered their national economies by accepting a model of capitalism imposed by Western societies that isn't tailored for their size and it is normal that the population of such countries are unhappy with the measures developed by the government.

All the theories about globalization lead us towards the idea of newborn imperialism, US imperialism in particular. It is considered the symbol of modern democracy and the modern capitalism creator, its influence is formed through values, methods, plans, models, etc. and especially by transnational companies that open new businesses in countries where labor is cheap. With products sold worldwide, synchronization occurs at cultural and economic level and it results in a pressure on countries that badly need foreign investment, this way forcing political change and, in some cases, more evident than in others. All these result in a paradox of capitalism and globalization that is based on the free market and democracy, but in the current economic climate needy countries from the political and economical perspective, are not part of this freedom of choice or action, there are being offered financial aid and also a set of values and principles of government that are generally, but not tailor made, while confining them the range of options and freedom of choice.

Few people dispute the benefits of open markets, but almost everyone agrees that they have been distributed unequally among other countries, therefore there are some countries that together with their increase of global trade and international capital flows, those countries also increase their sense of vulnerability (Yusuf, 2001). Many workers from industrialized countries are afraid of the international flow of labor, an exchange that interconnects cheap labor from developing countries with multinational companies that use options offered by globalization in their own interests, ignoring the interests and possible long-term benefits of the country in which they choose to operate and invest, for example we can analyze the case of Nokia that moved from Germany to Romania, and from Romania to India in a short period of time (under two years), because they had only one purpose: find the cheapest labor that can put together a mobile phone.

The most important component of the harmonious development of globalization is that the efforts of developed by aid recipient countries (Yusuf, 2001), composed from those values and ideas, directions and principles resist on the long run, but altogether without destroying the national identity, or the nationalist sentiment. Underdeveloped countries or developing ones are reluctant when it comes to globalization, even if they would generally benefit from it, because they sometimes estimate that they would be hit by disadvantages on short and medium term, this in a context where there is a massive lack of synchronization on other levels: cultural, political, social, and on the long-term those countries could overcome the shortcomings and economic loneliness. This is because globalization affects not only those that promote it, but also those who reject it, even as seen as the refusal to open the economy to the the world market because it generates loss of growth opportunities inherent in globalization and for those that try to protect themselves as a closed economy.

Major barriers that must be surpassed by developing countries to accede to the globalized world and to have access to development opportunities are cultural barriers, political and social. The cultural factor is the trickiest because new members of the globalized world must accept that elements of Western influence are needed to be assimilated (Dumea, 2016). On the other hand, they also enable integration into the national Western culture in a gradual manner, keeping their values and thus sheltering nationalist sentiments of the population. There must in any case be a balance, because otherwise, will develop strong extremist movements in society, there will be crises arising from complaints regarding the so-called "imperialism", slowing or stagnating evolution of society and the economy.

From the political point of view, countries need a clear and functional leadership structure, a strong democracy, bureaucracy and corruption should have very low levels, aimed at their minimum possible. This is very important because otherwise you can develop a situation like Romania’s case, which was after the Revolution very open towards globalization and the West, but was greatly weakened by a political class that did not follow uniformly the unanimous accepted development plan. In our case, the local political class, full of scandals, did not take the real economic potential of the country, especially in the first 10 years after the fall of communism. Therefore, it is imperative for developing countries to have political stability, because this stability linked with consistency in the actions of a state power leads to progress.

For globalization to be a harmonious and social synchronization it should be connected to the other three facets of globalization: cultural, economic and political. From this point of view, the society is seen as a whole unit, an organized system of relationships between people, located in a geographical and political status quo, also globalization is felt by a flow of products, information, knowledge and how Westerners live, this way the new globalized entities should adapt to these changes, integrating all these issues at the center of its own values and traditions. Gradually, social homogenization would gain momentum at the expense of separatist and fundamentalist sentiments. There must be a balance between absorption of Western culture and the preservation of traditions born on the idea of that the national identity isn’t kidnaped. Otherwise, globalization will be perceived by society as an aggressive phenomenon and tool for replacing values, resulting in its rejection.

The transition from communism to capitalism, filtered by globalization

Post-communist economies, including Romania had after the fall of socialism, to make a choice as transition from a centralized economy to capitalism, namely it had to choose between: shock therapy and gradual therapy.

The shock therapy, supported by the International Monetary Fund and the World Bank and presented by Jeffrey Sachs, is based on a set of recommendations and directions, also known as the "Washington Consensus" through which states must adopt in order to successfully make the transition to capitalism. Initially, this path of shock therapy has been promoted as the best solution to create a free market, believing that privatization will directly create market mechanisms that regulate the supply and demand without any governmental intervention. Liberalization and privatization were considered as fastest paths to the market economy.

On the other hand, the gradual therapy was the correction made in the coming years as replacement for the shock therapy. Pragmatism and realism led to this new transition tool known as the gradual therapy. Its followers claimed that the shock therapy inevitably lead to a massive decline in living standards since the position can not remove the state from the economy without huge consequences on the population. Also, economic institutions and mechanisms in a post-communist society must be modernized and subsequently completely replaced, if necessary, but in a gradual manner, one by one, as they increase their efficiency. The gradual evolution occurred practically in post-socialist economies that implemented shock therapy and who recognized deficits inefficiency by creating a new model of transition to capitalism.

Whichever path is chosen, most socialist countries after the 1989 Revolution, passed along to the capitalist model, each of them, although the processes wasn't easy to all the ex-communist countries, they had to overcome some specific difficulties of transition. Among these difficulties, perhaps the most important and the one that created the most discontent among the population is changing and modernizing the political and social system. Lagging when compared with Western countries, former communist countries had to go through a process of catching-up that still takes place today. Most obstacles and difficulties have arisen from the expectations the population had in terms of economic development in relation to the practical results that were underlining the weak political system, a young and inexperienced democratic system, in which the main actors were most often supporters of the old communist system.

Russia itself has followed the model of shock therapy, promoted by the IMF and the US, and this is the best example in terms of the great expectations had from this transition model and its failure. In Russia rapid privatization and liberalization was followed by the sudden collapse of the market and resulted in social imbalances and issues had with their public debt and deficits.

On the other hand, Poland is the country that registered the best economic results of the former communist countries from Eastern Europe. China also achieved the fastest growth of world economies in recent decades. However, China and Poland have not followed the instructions of the Washington Consensus, but followed their own economic development plan. Poland used the shock therapy at the beginning of the transition, but in the process they realized that it does not help with social pressure of inflation and also it does not lead to sustainable economic growth, so they went towards a policy of gradual privatization and creating simultaneously institutions that promote the market economy (Stiglitz, 2003).

China's success in the transition to a market economy contrasts with Russia's failure so that starting from 1990, China registered a growth of over 10%, while Russia has experienced a decline of 5.6% per year on average (Stiglitz, 2003), this increase economic led China to a considerable reduction in the number of poor (from 358 million in 1990 to 108 million in 2015), while in Russia, the number of poor increased in comparison with the darkest moments in history, the two World Wars.

Regardless of the method chosen by the transitional post-socialist countries, some successful models are seen, those of Poland and China, and shows that economic growth can be expected within a decade, but once you are developed you need to change your approach on policy making (that's why these two countries have lost their edge – Stiglitz, 2003). The economic gap between these states and the pure capitalist ones could be recovered whatever the disadvantages developed from the centralized economy, as long as it attaches importance to the private sector and decentralization, taking into account the cultural and social shock can develop social pressure seen on the and also that could regress economic development. The transition from communism to capitalism in general is a slow process, but it can have impressive positive effects and in a relatively short time if there is synchronization between the main pillars of globalization: political, social, economic and cultural.

Regarding Romania and the shock therapy used in its transition to the free market, after the Revolution of 1989, there was an euphoria towards the acceptance of capitalism, the market has been chaotic back then, due to the social and political pressure that the government must handle, but in the opposite of what they did in the past regime, the communist one: the lack of total involvement in the

economy, or the lack of a competitive market that doesn't allow the birth of the invisible hand, this way the capitalist way transformed into wild capitalism (Bodislav, 2012). Thus, Romania missed the start of the transition to capitalism because it wasn't capable of developing momentum immediately after the Revolution. Shock therapy is not an absolute solution to a market economy, but the indications of the Washington Consensus were not fully irrelevant. What was lacking most in Romania after 1989 was the will and tools to create a legislative and institutional framework that could evolve and deploy the market's development. Starting from the third millennium (the 2000-2005 timeframe) Romania developed the needed reforms and it accelerated forward until it joined the European Union on 1 January 2007, unlike Poland, which began with the shock therapy and continued with the gradual one and joining the EU in 2004 or Hungary, which used from the beginning the gradual therapy as a paced and sustainable transition method and succeeded in joining the EU along with Poland.

Romania's evolution starting with 1989

Lack of modernization of the institutional and legislative framework postponed rapid privatization and this way the full potential of the shock therapy was limited. The unemployment skyrocketed and this developed a strong social pressure on the Romanian government. The delayed transition to capitalism also entangled the chances of becoming a global player for Romania, so in other words, the market created after the Revolution was not competitive and stable and the big picture was blur when it came to transparency and efficiency.

For a clearer picture of Romania's transition to capitalism, we will analyze some economic indicators and developments for the period 1989-2014. The data for the year 2015 isn't finalized yet, so that is why we will use 2014 as an end date. First we will present the evolution of Gross Domestic Product growth and developments in the Foreign Direct Investment growth rate. In Romania, it has evolved positively since the Revolution of 1989 to present, stark fluctuations and a sharp drop in 2010, shortly after entering recession (Dinu, Bodislav, 2015).

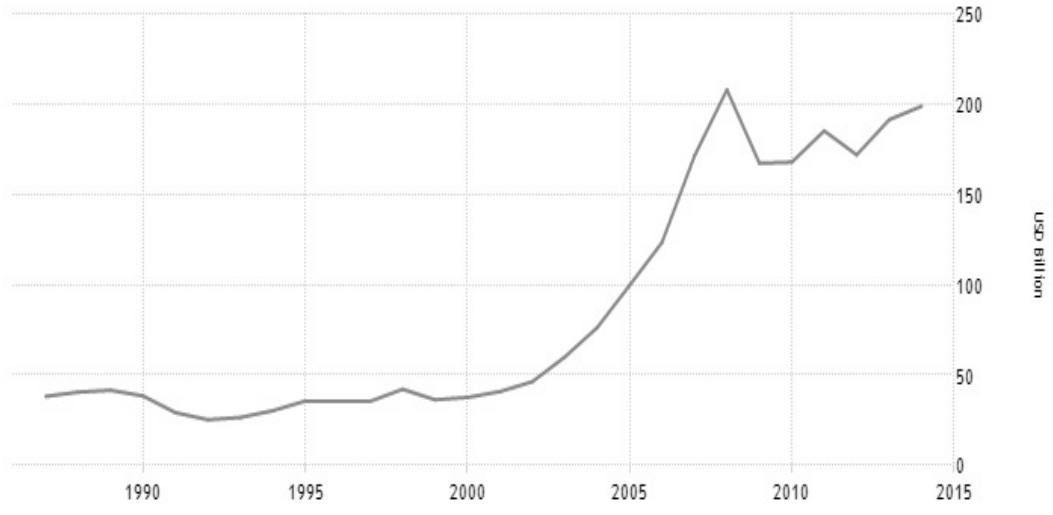

Fig 1. Evolution of GDP in Romania between 1989 to 2014 (2015 estimated)

Source: http://www.tradingeconomics.com/romania/gdp

GDP value expressed in the graph is measured in billions of dollars as the euro appeared only in 1999, replacing national currencies in the European Monetary Union in 2002. As can be seen, a slight decline in GDP in the period following the 1989 Revolution GDP sloping from 40.4 billion $ to 25.1 billion $ in 1993, due to the chaotic transition to capitalism in Romania, rebounding since 1996, when the Government realized that government intervention is necessary and It should not be left solely on

the regulation of the "invisible hand". With a GDP below 50 billion dollars in the early 1990s, this threshold was exceeded only in 2004, after which Romania has made significant progress in economic development and after its accession to the European Union in 2007, it can be seen that in 2009, Romania's GDP increased from 40.4 billion $, as it was in 1989 to 204 billion $ in 2009, this being the highest ever recorded by Romania in the last 26 years. Currently Romania's GDP is about 189 billion $ and for 2016 it estimated to reach its biggest value, surpassing the 210 billion $ threshold.

In terms of FDI (Foreign Direct Investment) value, it is important to analyze the degree of development of the economy since it highlights the stability of the business environment in a country, attracting foreign investors it shows sustainability of the economy and also stimulates the economy. Analysis of FDI is important from the point of view of economic engagement in globalization by the fact that foreign investors are the basic layer of the network that sustains the globalized world. The value of FDI in a country is determined annually.

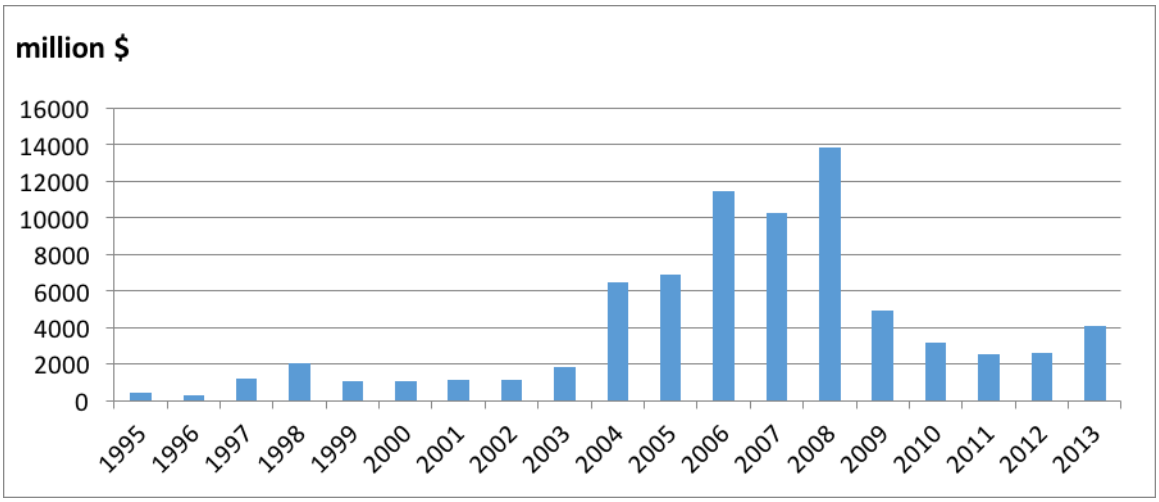

Fig 2. Foreign Direct Investment

Source: the authors by using the data available online at: http://databank.worldbank.org/data/reports.aspx?source=2&country=ROU&series=&period=

The beginning of capitalism in Romania in terms of FDI was insignificant in the first 5 years, because the business environment was inhospitable to foreigners due to the country's economic instability. Thus, the values shown in the graph expresses FDI in millions of dollars over the last 20 years, between 2014 and 2015 data are inconclusive. Therefore, the value of FDI in Romania in 1995 was 419 million $, Until 1998, reaching a value of about 2.031 million $. There was a slight decrease to a value of about 1.041 million $, and remained relatively constant at this value until 2004, when foreign direct investments in Romania have exploded, reaching in that year to 6.443 million $ and continued on an upward trend, peaking in 2008: 14 849 million $. After the recession of Romania, their value has dropped dramatically in 2009, to 4.926 million $ and fell to 2629 million $ in 2012. Since 2013 the value of FDI started to increase slightly to 4.108 million $. The gradual exit from recession, (re)stabilization of the business environment in Romania and also a more flexible fiscal policy, are the factors that attract foreign investors in the country since the economic crisis, investors that are absolutely necessary for reigniting growth and economic development, especially in the context of globalization.

To complete the picture analysis of the economy after the Revolution to the present, we must take into account the growth rate of real GDP per capita. This indicator is important because real GDP per capita indicates a country's standard of living, as it is also a method of measuring the average net income of the state. This indicator does not include the negative economic effects so it is not a precise indicator of a country's welfare, however we will analyze its growth rate from 1996 until 2014.

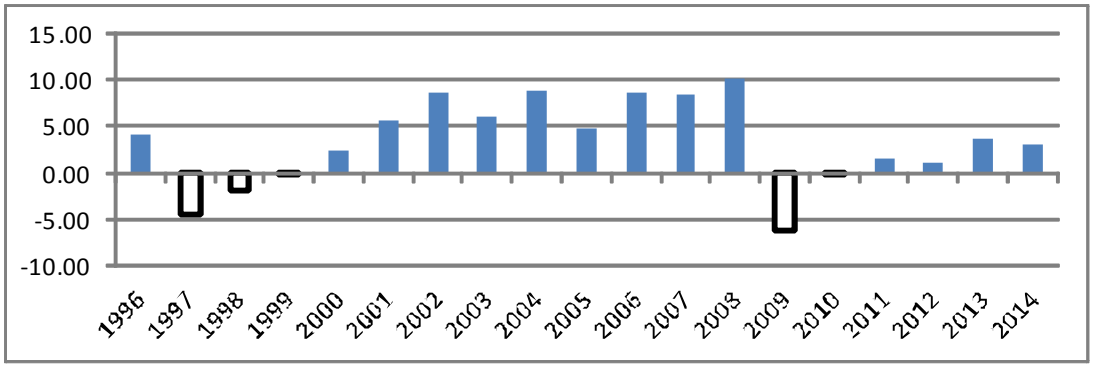

Fig 3. The growth rate of real GDP per capita (%); Source: http://ec.europa.eu/eurostat

As can be seen in the graph, the growth rate in Romania fluctuated until the early 2000s, from 4.2% in 1996 to a low of -4.6% next year until 2000 was still under the 0% threshold, but less: -1.9% in 1998 and -0.2% in 1999. Since the year 2000, the growth rate of real GDP per capita increased from 2.5% to 10.3% in 2008, and after the economic crisis, fell sharply to -6.3% in 2009. As of 2011, the growth rate of real GDP per capita began to increase, in 2014 reaching a level of 3%.

Conclusion

Countries that have made the transition from socialism to capitalism had and still have catching up to do from economically, politically and culturally vantage points. These ex-communist countries also enter the global economic cycle, but the differences seen in economic terms between them and western (capitalist) states makes the transition process weak. For a state economy that it is strong enough to be considered globally competitive, it needs stability at the political, legislative and social and cultural level. An unstable political system and an inefficient legislative framework will lead to an increase in corruption and failure to thrive, while the social development and harmonization of cultural cooperation it is extremely important because their absence would create social tension, which also leads to an inability to progress.

Globalization must be seen as an engine that streamlines also countries that have extreme political regimes, it resets them and clears them on the right path. In the third millennium it is obvious to most states that a political and economic cooperation is more advantageous than any kind of conflicts. China is a country that understands the benefits of globalization and as a result has adopted the motto: "one country, two systems", referring to the communist political system and a market economy almost the same with the capitalist type. Moreover, China transformed itself in the last 25 years in one of the major economic powers and is therefore an important player in the global economy and also could be seen as a role model for all states who refuse to enter the globalized world.

Another issue slowing down the process of globalization is obviously the recent economic crisis that broke out in 2008. This crisis has aggravated social problems existing in post-socialist states and emphasized the gap between the standard of living between the elite and the general population, "It is a system crisis which has affected not only the economy, but all sides of social life" (Bari, 2010). This crisis has affected the credibility of the capitalist system, but there is currently no alternative to this system. The only alternative in recent history was centralized economy, communism, and it was almost completely abolished and cataloged as absolutely wrong and ineffective, even China embraced the market economy, which gave it a look of its own, a unique model.

The economic crisis that began in 2008 reduced the international transfer of factors favoring the globalization process to slow down. This should not mean a halt for globalization, but a slowdown because economic networks formed over the last decades can not be completely destroyed by the economic crisis. Although many businesses have experienced failure in this crisis, economic relations between states and between business entities continued, so both the public and private sector have continued and continue to operate, but by providing a lower yield. Its effects have been disastrous for

some countries (Greece), which have led to social tensions and peaked at political level, extremist parties being elected, while in other countries (Poland) the crisis was weaker in deployment and technical recession was virtually nonexistent.

Globalization is necessary from economic, cultural and political perspective, especially in this new information age in which we are globally interconnected. Speed of information, goods transport and technological progress of the last five decades is a consequence but also a prerequisite for globalization. First, globalization could not take place, or the process would be much slower if we did not have these modern technologies which make possible connections between countries, companies and individuals, and it is these networks that are created by globalization and empowered by telecommunication technologies that allow even the weakest economies of the planet to get into the global framework (Bran, et al., 2012).

In the end, we could state that diffusion of technology from developed economies and industrialized countries to less developed ones represents an extraordinary opportunity to finally streamline globalization by developing the ability to assimilate the techniques, methods and advanced technologies and to fast-forwardly use them for the purpose of development and prosperity, raising living standards and creating a globally competitive economy.

Societal Human Resources Management and Development

Viviana Andrade Meirinhos, Polytechnic of Porto - Centre for Human Resources Research and Development (NID_RH), Porto, Portugal, vivivanameirinhos@eseig.ipp.pt

Ana Isabel Couto, Polytechnic of Porto - Centre for Human Resources Research and Development (NID_RH), Porto, Portugal, anacouto@eseig.ipp.pt

Abstract

Based on a broad conceptualization of Human Resources Management and Development (HRMD) as a technical, political, and strategic field concerned to managing and developing people within and towards work context(s), this research aims to explore a potential societal role of Human Resources (HR) profession. Framed on a larger project on "New Human Resources roles", this particular study approaches HR profession by analysing its macro-societal challenges and intervention spaces.

Keywords

Human Resources Management, Human Resources Development, HR profession, new roles

Human Resources and social-economic development

Human Resources (HR) are a key driver for regional development sustainability and global economic growth (Aksentijević & Ježić, 2014; Peschner & Fotakis, 2013; Vlad, Ungureanu, & Militaru, 2012). HR qualifications and its competencies profile represent some of the critical elements for a successful social-economic setting, assuming, for example, qualifications' levels of the population one of the central indicator of nations' economic development. Both by its tangible and intangible capital, HR are source of natural, social, political and technological progress. That is why a competitive and innovative knowledge-based economy and society strongly relies on its human capital (Eurostat, 2015).

Most of the international institutions (such as the Organisation for Economic Co-operation and Development (OECD, 2001), the International Labour Organization (ILO, 2014) or the World Economic Forum, 2016) agree that human capital - understood as the knowledge and skills - is essential for the economic success of nations as a whole and not just for the companies. This success is reached by the search of "new conditions of production and work" (OECD, 2001, p. 9)**,** which take place through HR "talent, know-how, skills and capabilities [... as the] key to economic growth" (World Economic Forum, 2016, para. 4).

HR Societal contemporary challenges

The recent economic and financial crisis brought new challenges to contemporary societies and governments, new pressures to social cohesion (EC, 2010) and to economic growth, affecting companies and people (ILO, 2016). Unemployment reached in 2015 197.1 million (approaching 1 million more people than in the previous year and over 27 million higher than pre-crisis levels (ILO, 2016); professional exclusion and proliferation of vulnerable employment accounts for 1.5 billion people - over 46 per cent of total employment (ILO, 2016); atypical (and precarious) forms of work; Youth neither in employment nor education and training (NEET) (EC, 2010); demographic changes; persistent gender inequalities, with women still facing "25 to 35 per cent higher risk of being in vulnerable employment" (ILO, 2016, p.3); age_discrimination, with a labour market not receptive to *young* old people; the growth of a working poverty (ILO, 2016); migration and the recent refugees phenomena are just some of the social-economic materializations of this setting.

Modernising labour markets, promoting labour quality and empowering people by developing their skills throughout the lifecycle with a view to increase labour participation and better match labour supply and demand are some of the current challenges to face these changes and structural problems.

Societal Human Resources Management and Development: Contributions to new HR roles

The role people as labour resources play in social-economic development, and consequently the multiple HR challenges contemporary societies face, set necessarily HR management and development (HRMD) with a central assignment in the current work paradigm. Effective management and development of a nation's HR performs, in this context, as a crucial process in social-economic growth and sustainability.

This setting claims a deep debate on HRMD rationales within HR academic, professional, and educational communities. New challenges, and new tasks require inevitably new roles for HR professionals, new research problems to academics, and new educational contents in HR training and professionalization. HR profession has to be itself challenged to assume new functions in these new scenarios.

Grounded on the proposition that is not possible to disregard HR cumulative knowledge and HR specific competencies to face this macro-structural conjuncture, this research aims to bring to the scientific debate the role HR may and shall undertake within a societal level. Going beyond its traditional roles restricted to the organizational context (Thill, Venegas, & Groblschegg,2014; Thite, Budhwar & Wilkinson, 2014), territories, communities, sectors, professional domains and other social-economical clusters are conceived as potential societal approaches to HRMD. Categories, such as "work/labour/ employment" or "training/ education/ qualifications" emerge, in this framework, as

pure HR macro-social categories, and not only as labour market contextual categories to organizational HRMD.

In order to explore this conceptual starting point, this research defined as specific objectives (i) characterizing HR macro-societal challenges; (ii) identifying existing HR societal interventions; (ii) identifying HR societal roles; and (iv) conceptualizing adapted mobilization of HR specific processes (considering specific resources, instruments, and practices) to macro-societal challenges.

It is expected that this empirical study contributes to HR profession development, alongside to the identification of research problems within SHRMD as to the identification and promotion of HR educational knowledge driven from the identified HR working knowledge needs.

Enhancing IT Intrapreneurism in Big Pharma: Incorporating Human-Centered Design at Merck Consumer Care

Brian D. Janz, University of Memphis, Memphis, Tennessee, USA bdjanz@memphis.edu
M. Jeff Brittain, Merck Consumer Care, Memphis, Tennessee, USA

Abstract

Top concerns for IT leaders for the last 30 years include becoming/remaining relevant to the overall business, developing a strong and healthy relationship with their end-user community, being viewed as the organization's innovation thought leader, and delivering systems that surpass end-user expectations, on time, and within budget. Adopting an intrapreneurial mindset within IT is one way to achieve these goals. The premise presented in this paper is that Design Thinking -- or more specifically "Human-Centered Design" -- is a process and mindset that will help create a more intrapreneurial culture in pre-existing large organizations. In the paper we outline the major tenets of design thinking: a focus on human values, radical collaboration with the end-user, empathy-driven requirements determination, a relentless focus on the end-user's point-of-view, and rapid prototyping/story-telling in close proximity to the end-user coupled with user testing. In addition, we present a chronology of how Human-Centered Design has shaped the innovation process at a large consumer-based pharmaceutical firm and how design thinking is now serving as the basis for energizing the company's IT organization and its end-users in driving real business value.

Keywords: Innovation, Intrapreneurism, Design Thinking, Pharmaceutical

Introduction

Intrapreneurial behavior – that is, having employees within an organization behave like entrepreneurs – has been linked to improved organizational innovation according to Park, Kim, and Krishna (2014), as well as firm performance according to Antoncic and Antoncic (2011). Furthermore, Benitez-Amado, Llorens□Montes, and Perez□Arostegui (2010) suggest that this connection applies within the IT context as well. Therefore, it seems reasonable for IT executives to find ways to help foster intrapreneurial behaviors within their organizations.

This effort seems all the more reasonable when one considers that the Society for Information Management (SIM), through a series of commissioned studies over the last few decades (for example, see Brancheau, Janz, and Wetherbe's "key issues" study (1996)), has learned that IT leaders have repeatedly identified the following issues that may also be addressed by a more innovative and intrapreneurial IT organization:

- Aligning IT strategies to better match their business's strategy
- Creating more responsive IT organizations in terms of IT service delivery as well as time to market with IT-enabled products and services, and
- Improving the standing and relevance of IT organizations within their respective businesses.

This paper argues that Human-Centered Design (HCD) – a novel, user-centered design and development process – may serve address the needs for improved firm performance and innovativeness as designers and developers begin thinking more like intrapreneurs who promote innovative product development and marketing efforts. In addition, as HCD is known to serve as a means to enhance the ability of design teams to better understand their customers, and to help the designers deliver products and/or services in a more timely manner, it may also serve to address the key IT issues described above. Finally, as a by-product of the HCD approach,

Merck and Company ("Merck") is one of the largest pharmaceutical companies in the world, and is headquartered in the U.S. Their product line includes vaccines, prescription and oncology pharmaceuticals, veterinary medicines, and consumer health products. The Merck Consumer Care subsidiary oversees a broad product line of consumer-based and over-the-counter products, including well-known brands like Dr. Scholl's®**,** Coppertone®**,** Afrin®, and Claritin®**.**

In this paper we outline how Merck Consumer Care's IT organization has adopted HCD as a way to improve its innovative capacity in product design, its responsiveness to its end-user and customer community, and in so doing has created a more intrapreneurial culture and elevated its leadership stature within the Merck Consumer Care organization. We offer the insights gained in their HCD journey – in terms of best practices and lessons learned – and suggest that other IT organizations can derive similar benefits by incorporating the ideas and approaches inherent in design thinking.

The Role of Human-Centered Design in Addressing Perennial IT Challenges

As alluded to earlier, IT organizations have long faced a fairly static list of challenges as evidenced by results in numerous SIM "key issues" studies. One of these challenges includes configuring the IT organization's mission, goals, and strategies to be more closely aligned with the mission, goals, and strategies of the overall business. Such alignment, it is posited, enhances IT's ability to assist the organization in meeting its goals and objectives in the most efficient and effective manner possible.

A second time-honored challenge includes issues related to the provision of better service to the broader company and ultimately its customers. These issues include being more flexible in responding to the dynamic nature of end-user requirements for new or enhanced IT platforms as well as being more agile in responding to changes in business climates and customer tastes and preferences. The logic here suggests that if the IT organization can possess this kind of agility, they will be better positioned to deliver IT-related products and services to their end-user community in a more timely manner, which will then translate to the IT organization being able to positively affect the overall organization's time-to-market – the ability to deliver new products and services to the ultimate customers more quickly.

A third perennial challenge relates to improving the perception of the IT organization vis-à-vis the other functional areas in the organization. This has been portrayed in a myriad of ways, from having the IT organization being viewed as the organization's thought-leader for innovation, to viewing IT as a new source for the organization's revenue stream.

In essence, these three challenges can be met if the culture of the IT organization were more intrapreneurial in nature. That is, if employees were to view their efforts within a context of being more autonomous and innovative in how they design, develop, market, and deliver IT products, all stakeholders – the IT organization, the larger corporate organization, and the end-using customers – would all be better served. We believe HCD can help achieve this intrapreneurial mindset. In the next section, we introduce HCD in more detail, and discuss how it specifically addresses these IT challenges. Following that, we illustrate how Merck Consumer Care's IT organization has achieved positive results by adopting an HCD mindset in its system development efforts.

A Human-Centered Design Primer

HCD is an offshoot of a school of thought known as *design thinking*. Depending on whom you ask, you may hear that design thinking is a mix of scientific thought and artistic thought applied to problem solving, where the problem is coming up with a functional and innovative design. In fact, design thinking is a broad and amorphous concept, with an equally broad heritage.

The History of Design Thinking

Some embrace the notion of "design" from an artistic perspective – fine arts, graphic arts, etc. – and the history of these origins can be traced to archeological artifacts at the dawn of humankind. Interestingly, the field of IT played an important role in the evolution of design when Herbert Simon's "Sciences of the Artificial" introduced a scientific approach to design, where design process is conceptualized as a problem-solving task. At about the same time, the concept of "visual thinking" emerged in the field of psychology and can be seen in the book by Rudolph Arnheim (1969) and later in the engineering domain at Stanford University, as seen in the book by Robert McKim (1973).

More recently, today's notion of design thinking as a creative and innovative endeavor can be traced to follow-on efforts at Stanford, most notably Horste Fast and his colleague David Kelley. Here the focus of design continued to evolve on campus (at Stanford's "d.school"), as well as within Kelley's design firm, IDEO. Probably as a result of IDEO's mission to aid its clients in coming up with innovative solutions and the d.school's mission to educate its participants in innovative design, design thinking began to be equated with innovation. Today's design thinking has taken on a more human-centered flavor, and is often referred to as "Human-Centered Design", due to it's emphasis on engaging the user/customer/consumer early and often in the design process[1].

HCD *Today*

The Stanford d.school's version of HCD can be broken down into the following five steps as illustrated in Figure 1:

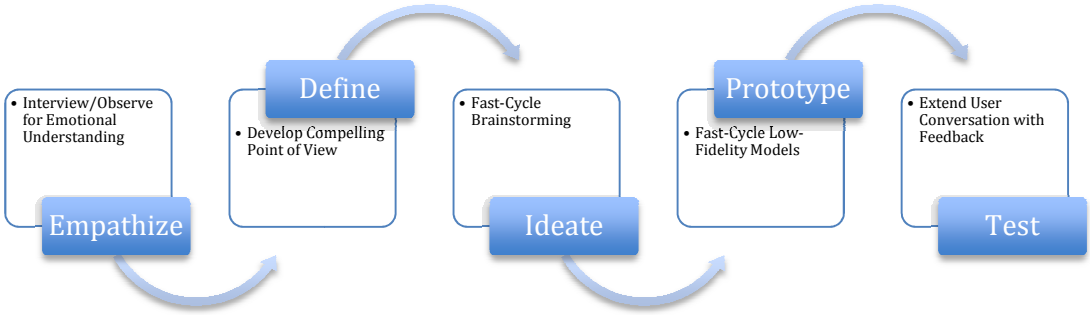

Fig 1. 5-Step Process for Human-Centered Design

During the **Empathize** phase, designers immerse themselves in the world of the customer in an attempt to understand their challenges, needs, and desires pertaining to a certain "design challenge" faced by a user or community of users. As part of the process, designers first observe users within the context of interest, develop hypotheses as to what the challenge is, and then engages the users through field-based intercept interviews in an attempt to gain an empathic understanding of the user perspective an emotional level. For example, rather than just soliciting the user for a list of needs and requirements, the designer will push the user to share *why* they have these needs, and *how* meeting or not meeting these needs make the user *feel*. Asking the user to share personal stories related to the challenge is one way to achieve empathy during this phase, and is the essence of the "human-centered" nature of HCD. Typically, after this phase, the designers will have a collection of such user stories.

The **Define** phase is akin to the problem definition phase of the traditional problem-solving process, but rather than defining the problem, the designers use the stories collected from the Empathize phase to generate a *point of view* (POV), which describes a typical user with a unique set of needs within the context of interest, along with insights related to why meeting the needs are compelling.

The **Ideate** phase is similar to traditional brainstorming in an effort to generate as many innovative ideas related to the POV as possible. They typical rules of brainstorming apply here: go for quantity of ideas, don't judge the value of the ideas too early, encourage a diversity of perspectives, etc. It is in the Ideate phase that you strive to experience the radical, collaborative energy of the design team.

The construction of tangible potential solutions occurs in the **Prototype** phase. Here the emphasis is on building physical models that embody the most promising ideas revealed during the Ideation phase that can be shared with users, as opposed to just telling users about the ideas. "Show, Don't Tell" is the mantra during this phase.

Once a prototype is constructed, the process moves to the **Test** phase where the prototypes are shared with users, feedback is received from the users, and the prototype is iteratively further refined and shared again with users for additional feedback. Adopting an experimental mindset is important here in that failed prototypes are valued for the additional information they help to provide.

The HCD-IT Relationship

Upon inspection of Figure 1, one might surmise that HCD is similar to many product or system development processes, including the traditional "waterfall" approach. In practice, HCD is more similar to agile development methods, for its incremental and iterative prototyping approach and close working relationship with the user. However, HCD sets itself apart from Agile methods in its focus on empathizing at an emotional level with the user as well as its relentless focus on innovation throughout the process.

In terms of the IT challenges introduced at the outset of the paper (better IT alignment, improved IT agility, responsiveness, and delivery, and improved relevance and innovation from IT), it is clear that HCD has the potential to play an important role in addressing them.

First, from an intrapreneurial perspective, spending a significant amount of time and effort on the front end in gaining a deep, empathic understanding of the user in terms of their challenges, desires, and needs helps the IT organization better understand their "market." From an IT perspective, this enhances the chances that the designer/developer will gain a better appreciation of both the articulated and un-articulated goals, objectives, and strategies of the user community, which can only help in better aligning IT with the rest of the organization. Similarly, the prototyping approach espoused by HCD is focused on learning rather than confirming design specifications. This too should help with alignment.

Second, the focus on rapid, iterative prototyping enables the IT organization to be more responsive and better able to deliver solutions in a timely manner which can also positively affect the larger organization's time-to-market. Having an appreciation for "time-to-market" is another consideration important to entre/intrapreneurs.

Third, HCD is first and foremost known as an effective way to design and develop innovative solutions to address market-driven problems as well as capitalize on market-driven opportunities. Taken together, these elements serve to create a more intrapreneurial way of thinking for the IT organization. This can only help in elevating how the IT organization is perceived in terms of its ability to serve as a thought-leader for innovation as well as a potential contributor to new sources of revenue.

In the following sections we will introduce Merck Consumer Care's IT organization in more detail along with how the organization adopted HCD, and discuss what benefits accrued to Merck Consumer Care as a result.

Merck & Company

At the time of this writing, Merck & Company (known as MSD outside of the U.S.) is a $44 Billion global healthcare company operating in three general lines of business: Pharmaceutical, Animal Health, and Consumer Care. The Merck Consumer Care (MCC) business develops and sells nearly 1600 products around the world in the areas of upper-respiratory care (e.g., Claritin®, Afrin®); sun-care and therapeutic skincare (e.g., Coppertone® sunscreen); digestive health (e.g., MiraLAX®); and foot health (e.g., Dr. Scholl's®).

MCC has deep history in developing innovative products to help people take back their lives. This history is very entrepreneurial in nature and begins in 1908 in Memphis, Tennessee when Abe Plough created the Plough Chemical Company where he manufactured and sold "Plough's Antiseptic Healing Oil," and quickly grew to include St. Joseph's children aspirin[2]. Throughout the next 100 years, this business has created many innovations that have literally changed the way the world works. These innovations include developing the scientific measurement known as the Sun Protection Factor (SPF) that is now a global scientific standard, using open innovation to bring technology from other industries in revolutionizing sun-care again with the continuous spray bottle that works at any angle (so we can protect our wiggling children and our own backs), launching the first ever drug to move from prescription to over-the-counter "Rx to OTC" in the US with Coricidan®, and continues today with Dr. Scholl's® Custom Fit Orthotics self-service kiosks.

Over these same years, the Plough Corporation grew through a merger in 1971 with the Schering Corporation to create Schering-Plough, and later became Merck Consumer Care in 2009 after Merck acquired Schering-Plough as a means to diversify Merck's business.

Prior to the acquisition by Merck, the IT function for MCC was initially part of the larger pharmaceutical business and was steeped in traditional IT methods, including the company's standardized software development life-cycle (SDLC), which codified the time-honored waterfall development process. The traditional IT structure was further hardened by historical views of how Health Authorities, the Food and Drug Administration (FDA) in the US in particular, view the proper control of electronic records and IT development in general.

In 2010 with the formation of the "Merck Consumer Care" (MCC) business unit within Merck, MCC established a direct team of IT professionals to focus on the consumer business and changed the way IT was viewed by bringing it closer to both its internal and external customers.

Merck Consumer Care's Intrapreneurial Journey with Human-Centered Design

Like many organizations, MCC found that the historical ways of creating innovation were increasingly less effective (and less entrepreneurial) in driving significant revenue growth. The company was very adept at driving "product-centric, incremental innovation," a.k.a. nuanced changes that were focused on the product: a slightly higher SPF sunscreen, a new flavor of children's cough syrup, melt-in-the-mouth tablets, etc. To be certain, incremental innovation was a very real and meaningful driver in growing the company's portfolio, but MCC executives realized that without more "Big Bang" or "New to the World" ideas, Merck's future revenue growth would decelerate over time.

To address the need for more breakthrough ideas, MCC benchmarked what successful innovative companies were doing. They soon learned that for innovation to be meaningful, it had to be centered on the consumer, the person. When the innovation arm of MCC's R&D division was first introduced to HCD at a Stanford University executive seminar, they knew that they were on to something.

While MCC was changing the business development process from product-centric to consumer-centric innovation, Merck was also changing the role of IT in the business. Historically, IT was

managed under the general governance of the Pharma business and its work fit traditional patterns. In this traditional pattern, the business comes up with strategy and annual objectives, and IT does its best to align its objectives and support the business. Driven by user requirements and user requests, the technology team focused on site-specific initiatives and tended to be geographically focused.

The MCC IT leadership team set off with a strategy to bring value to the MCC business by: a) embedding the IT leadership personnel within business teams, b) focusing on innovation, and c) providing the business with deeper understanding of the "end-to-end" business process. As such, HCD became a catalyst for these changes to the IT function. Rather than focusing on software applications maintenance and enhancement, MCC IT's organization started thinking about what new innovations IT could bring to MCC's business. Rather than looking to just automate existing business processes (a traditional IT approach), MCC's IT leadership began to focus on driving real product design.

Human Centered Design in Action: The Case of Dr. Scholl's®

One case in particular demonstrates the value of HCD to the MCC business and to the MCC IT function: Dr. Scholl's®. Similar to Plough's entrepreneurial beginnings, the Dr. Scholl's® brand began when William M. Scholl invented the category with his groundbreaking podiatric research in the early 1900's. In 2004 Dr. Scholl's® redefined the category again with the Custom Fit Orthotic Kiosk (CFO), helping millions of people get close to the benefits of a custom orthotic with a graduated matrix of products, fit to the person through a proprietary foot-mapping process. These CFO's could be found in large U.S. retail department stores and pharmacies.

HCD Design Phase	Phase Activities Carried Out by the Merck Design Team	Relevant Vignettes, Quotes, Etc.
Empathize	MCC's best practice "consumer center" allowed the team to not only engage in individual interviews and group focus groups, but also allowed them to observe potential users using existing and prototype products. Observation is a key component in inferring feelings, emotions, thoughts, etc.	User comments prove very helpful in this phase when using the current CFO product. A woman remarked that, "…current options are too bulky and can't be worn with normal shoes," while a man said, "I can can't get the right level of support. None of the current options fit someone my size."
Define	After collecting large amounts of user data, the team began to get a picture of the types of consumers they might serve with the CFO kiosk. For example, one user segment included females with chronic foot/leg pain that have given up on traditional healthcare and are now looking for do-it-yourself care options that also provide some level of advice.	POV statements typically refer to a specific type of user with a specific need. One especially compelling POV focused on an injured woman that needed a way to keep working because her elderly mother counted on her for physical assistance and help around the home. Understanding user needs at this emotional level helps to deeply engage developers and results in very compelling "use cases."
Ideate	Brainstorming sessions were largely co-creation sessions, i.e., potential users worked along side MCC staff to come up with innovative solution ideas for both the CFO kiosk and the user interface.	The need for some level of advice on future products became apparent when a gentleman commented, "I get confused at the shelf, I don't know what product would be best for me." This helped the MCC team understand the level of information that the user interface needed to provide.

Prototype	Low-fidelity prototypes of the orthotics, the kiosk, and user interface were co-created with basic art supplies in order to "show" ideas vs. only talking about ideas. Fast-cycle iteration was the norm; ideation-prototype-test cycles were often completed in one day. Over the course of 3 weeks, the MCC team completed 10-12 iterations.	When working with the kiosk's interface, one gentleman wondered if he, "…could customize the level of support" he received from the interface, again pointing to the need for advice from the kiosk. In terms of direct orthotic testing, one woman mentioned that she, "…wanted something that is sleek and easy to wear with my normal clothes." Interestingly, men seldom mentioned this concern.
Test	Potential users were encouraged to interact with the CFO kiosk, the user interface, and the orthotic products in MCC's Consumer Center. Two versions of usage were tested -- one where users could ask questions about the prototypes, and one where users were not allowed to ask questions, and were instead encouraged to figure out how to best use the prototypes. After Consumer Center testing, users tested the prototypes in in-store settings.	"I can't trust a solution unless it gives me the same answer no matter how often I try it..." suggested that the CFO kiosk system not only had to provide advice, but was going to be assessed by some consumers as to the reliability of the advice provided.

Fig 2. HCD Phases with Attendant Activities and Vignettes

As the years passed, MCC knew it was time to further innovate on the CFO platform (both the kiosk and the kiosk's user interface (UI), and enlisted the tenets of HCD to do so. During the Empathize phase, the IT team worked as part of the joint business team to understand how a variety of consumers think of themselves in the context of physical mobility. This included observing actual consumers describe their individual situations. In this phase, the MCC joint business/IT team looked for "extreme consumers" e.g. people who rarely or never use a Dr. Scholl's products as well as people with chronic, all-day needs for the products. Armed with this empathy data, the joint business/IT team defined a design "point of view" (the POV is akin to defining the problem), and set about developing several hundred alternative solution paths, starting with the original hypothesis of moving to a truly customized insole.

The MCC team then rejoined with consumers to ideate on variations of these paths. This close working relationship where designers/developers work with potential users is central to HCD and is known as co-creation. These co-creation sessions were conducted during the Ideation phase, and continued through the Prototyping phase were the MCC/user team created low-fidelity prototypes – rough sketches as well as quickly-built models using readily available, inexpensive supplies like paper, tape, pipe cleaners, etc. – to test with consumers. The benefit of testing low-fidelity prototypes with consumers is that the MCC team learned more about what the consumers liked and disliked, and in the process kept the consumer-developer conversation active.

As a result of numerous, fast-cycle ideation/prototyping/testing iterations, it became evident that the team's original hypothesis resonated with consumers *less* than the existing CFO product offering. The HCD process elicited new, alternative solutions that garnered not only a higher positive emotional response from consumers, but also would move the brand into adjacent product categories and expose the product line to a new untapped customer base. As a result, the original hypothesized solution approach was replaced with one that more deeply resonated with consumers. Ongoing market testing suggests the new product will result in a significant new revenue stream. See Figure 2

for a summary of MCC activities as well as short vignettes that illustrate what users were experiencing in each HCD phase.

Benefits to MCC's IT Organization

HCD has had several benefits for MCC IT: The first and foremost is IT's new-found, intrapreneurial role in driving business value. The solution resulting from HCD relies heavily on IT-enabled systems, and the IT-business revenue linkage has been significantly strengthened within Merck.

MCC IT's role as revenue driver has also heightened the perception of their relevance to Merck. Because HCD requires a radically diverse team from many functional areas of Merck (including IT) to engage in co-creation with consumers, the IT organization moves from the background to the foreground. The MCC IT team has found that rather than beg to attend meetings, they are now "required" to attend -- held accountable for significant timetables that have direct line-of-sight to the company's mission and revenue.

A third and equally significant benefit is purpose. Teams working in an HCD environment enjoy their work, are committed to helping consumers, and find deeper meaning in what they do each day. In one example, a team member commented during a period of business uncertainty that their work on one HCD project kept them loyal to the company.

Benefits to MCC

Adoption of HCD has changed Merck Consumer Care in profound ways. First, the company changed the way they evaluated innovation. MCC began to understand that the traditional measures of value for incremental innovation do not apply to breakthrough innovation, i.e., the gestation period for breakthrough ideas often result in lagged realized revenue streams. To prevent the seeds of ideas from being stopped in their tracks, MCC changed their early stage gate criteria to make it more appropriate for early stage ideas to survive.

MCC also changed the way work was structured, as well as where the work took place. Recognizing this, MCC created a set of innovation hubs. These open space work areas where employees from all levels of the organizational hierarchy work together have greatly increased the interaction between personnel, increased the amount of fun people have, and significantly reduced the number of formal meetings people scheduled.

Finally, MCC changed their organization by creating a team of innovation "navigators" charged with helping to build HCD capabilities throughout the company. These navigators are very much intrapreneurs in the true sense of the word. All in all, these changes have increased our product pipeline by 300% and established the company as a leading innovator among its peers. At the time of this writing, it is public knowledge that Bayer Healthcare has agreed to purchase Merck Consumer Care for $14.2 Billion USD. This transaction, one of the largest in the industry and at one of the largest earnings multiple ever in this industry is due in large part to the innovative culture and processes developed at MCC. Adoption of HCD literally made all of this possible.

Discussion

As MCC matured with the HCD process, we found some recurring themes that may be helpful for others pursuing this intrapreneurial approach. First, the HCD process more clearly discovers both articulated and un-articulated wants and needs. As such, the solutions identified will often be new-to-world or new to the organization. While HCD intrapreneurs will be somewhat accustomed to these breakthrough ideas, the rest of the organization may not. Patiently working with them to see the value of these potentially disruptive innovations is often necessary. On a related note, it is very important to involve key business and process owners early in the effort. Otherwise, the business could reject a truly breakthrough result.

In addition, the HCD team will benefit greatly by being interdisciplinary in nature and by including a wide range of types of thinking – some that are often not on staff. For example, spending the money to bring anthropologists and graphic designers on to the team, especially on first efforts, is money well spent. Finally, HCD's focus on the drive for quick results and conclusion on real business objectives helps to enroll stakeholders in the new process. Nothing enrolls others faster than a win.

Concluding Thoughts

As discussed at the outset, IT has long been looking for ways to more closely align themselves with the business, drive bottom-line revenue, be more understanding and responsive to its users, and be viewed as a true peer with other functional areas of business. Merck's HCD journey presented here suggests that by adopting this innovative type of design thinking, IT departments will begin to behave more like intrapreneurs, and will have an important role to play in their organizations as they seek out innovative solutions to drive future performance.

Often, product development initiatives are driven by marketing, R&D, or product line areas of the business. Given IT's long history in understanding systems development, requirements analysis, and prototyping, there is no reason why they can't pick up the HCD mantle and lead future innovation efforts in any organization.

[1] The Hasso Plattner Institute of Design at Stanford University (the "d.school") has done much to bring design thinking concepts to the world through their design thinking "bootcamps" (http://dschool.stanford.edu/).

Abstract

This research article represents a review of Romania's case on how it's economic growth evolved starting with the economic crisis from 2008 (it started later in Romania, because the country wasn't directly involved in the systemic failure) and how it pressurized socially the economy and political will.

The paper tries to analyze the following macroeconomic indicators: GDP, GDP per capita, inflation and the output gap by offering a big picture perspective on each of them, and how they come together in offering macroeconomic perspective on Romania's health and social evolution.

Keywords: crisis, GDP, inflation, output gap

Introduction

A couple of years before the crisis, Romania had an excellent trend for economic growth. Much of the increase lately was due to the aid received from the European Union through cohesion funds, funds developed for helping Romania have a successful catching up process. These grants were meant to help develop the technology used to increase country's production and productivity, and also to attract Foreign Direct Investments.

Thanks to the aid received from the European Union, Romania has managed to develop several economic sectors, by developing the technology used for businesses and also through some institutional reform which led to attracting foreign investors. These grants have led the country into economic growth, as production was increased due to the evolution of technology and consumption also increased due to higher wages.

During 2005-2008, prices were rising, but the rate was smaller then the average salary. The inflation rate was maintained into the established parameters according to the targets negotiated with the European Union, but also due to changing the monetary policy strategy from targeting monetary aggregates to targeting the inflation rate. This strategy has been changed due to the necessity of releasing the pressure developed by market factors that were pushing the prices up and also because this a better approach on developing financial stability in the Romanian monetary system.

Analyzing Romania's macroeconomic indicators

Since 2004 the Gross Domestic Product has had an increasing trend, from 290,488.8 million lei in 2004 to 666,637.3 million lei in 2014. In 2009 it had a slight decline due to the crisis compared to 13865.9 million lei previous year, but recovered quickly in 2010, an increase continued until 2014.

Gross Domestic Product analysis

From the following table we see that the GDP had growth rates increasingly larger year of year until 2009, when the crisis began. Until then, growth rates were quite high, over 15%, while by 2009 they were quite small, between 4% and 7%. From here we can see reduced growth, which began starting from 2010.

Table 1: Analysis of GDP, 2004 – 2014 timeframe

Year	GDP (million lei)	GDP growth compared to previous year (%)
2004	248,747.6	-
2005	290,488.8	16.78%
2006	347,004.3	19.45%
2007	418,257.9	20.53%
2008	524,388.7	25.37%
2009	510,522.8	-2.64%
2010	533,881.1	4.57%
2011	565,097.2	5.84%
2012	596,681.5	5.58%
2013	637,583.1	6.85%
2014	666,637.3	4.55%

Source: NIS GDP income approach, current prices 2004-2014, www.insse.ro, own calculations.

The largest increase in GDP was recorded in 2008 when it grew by 25% yoy. This increase was before the crisis, during the boom. In 2009, Romania recorded a GDP lower by nearly 3% over the previous year, the only year in which the GDP declined.

In 2009 it is observed that after the increase in the Romanian economy in recent years, there has been a decline in GDP due to the crisis. This crisis was felt hard in Romania because the country's population had expectations of growth year on year that will beat the trend each year that passed. This is not beneficial when crisis emerge, because the faster the growth, the faster the economy suffers more than usual (or similar socio-economical shaped countries) during the crisis and recovers harder after its passage.

Gross Domestic Product per capita and inflation analysis

After the crisis began a period of economic recovery starting with 2010. When the GDP surpassed the freefall during the crisis, one in 2008 and has continued to evolve until 2014 and with premises for 2016 and beyond. This development was lighter than the pre-crisis period because growth is smoother these days, but also insignificant. After the crisis, the GDP rose slightly, slowly, with very small differences between years, so this way seeing a more difficult recovery of the Romanian economy.

Table 2: GDP per capita analysis (euro, per capita)

Year	GDP per capita (euros per capita)	GDP growth per capita over the previous year (EUR)	Per capita GDP growth (% yoy)
2005	3,800	-	-
2006	4,600	800	21.05%
2007	6,000	1,400	30.43%
2008	6,900	900	15%
2009	5,900	-1.000	-14.49%
2010	6,300	400	6.77%
2011	6,600	300	4.76%
2012	6,700	100	1.51%
2013	7,200	500	7.46%
2014	7,500	300	4.16%

Source: Eurostat, GDP per capita 2005-2014, ec.europa.eu/eurostat

In 2005 GDP per capita was 3,800 euros. It kept an upward trend until 2009, when it fell from the previous year with 1,000 euros per capita, recording a value of 5,900 euros, compared to 2008 when it was 6,900 euros per capita. Further, after the crisis period, the GDP per capita continued to grow till 2014 when it reached a value of 7,500 euros. Since 2009 it has had an increase milder compared to the 2005-2008 timeframe in 2013 managed to exceed 2008 levels, so the initial recovery was reached.

From the table we can observe that from 2006 to 2009 the GDP per capita has grown increasingly more than 15% from a year earlier. In 2009 it fell by 14.49% yoy, due to the crisis. After the crisis period, starting with 2010, it grew less, with percentages ranging between 1% and 8%. In 2012, GDP per capita grew the least, an increase of 1.51% compared to 2011, while in 2013 it increased by 7.46% compared to 2012, which is the largest rise GDP per capita after the crisis, a result important for the entire European Union and its 28 members. Between 2010 and 2012 the authors observed that the increase is decelerating, from 6.77% in 2010 and reaching 1.51% in 2012.

The largest increase in GDP per capita was in 2007, when it increased by 1,400 euros from a year earlier, when the value was 4,600 euro per capita. The difference between the two years was 30.43%, a huge difference, highlighting the economic boom (and a possible over heating of the economy, which also could present us negative aspects on the long run). These increases situated at higher level than usual were not good for Romania during the crisis because the country was hit harder due to its peaks before the crisis, creating a visible decline of the indicator in 2009, during the crisis.

After exiting the crisis, the GDP growth per capita was less paced, it increased by more than 10% each year. The lowest growth after the crisis was in 2012, when GDP per capita grew only by 100 euros compared to 2011. Due to the low level increases, the GDP per capita in 2008 was surpassed in 2013, four years after the onset of the crisis. This was possible due to increases of 500 euro per capita gross domestic product compared to 2012.

Table 3: Inflation analysis, 2004 – 2014 timeframe

Year	Inflation rate	Changing inflation over the previous year (%)	Changing yoy inflation (percentage points)	Inflation target
2004	11.9	-	-	-
2005	9.1	-23.52	-2.8	7.5 (+ - 1pp)
2006	6.6	-27.47	-2.5	5.0 (+ -1pp)
2007	4.9	-25.75	-1.7	4.0 (+ -1pp)
2008	7.9	61.22	+3	3.8 (+ -1pp)
2009	5.6	-29.11	-2. 3	3.5 (+ -1pp)
2010	6.1	8.9	0.5	3.5 (+ -1pp)
2011	5.8	-4.91	-0.3	3.0 (+ -1pp)
2012	3.4	-41.37	-2.4	3.0 (+ -1pp)
2013	3.2	-5.88	-0.2	2.5 (+ -1pp)
2014	1.4	-56.25	-1.8	2.5 (+ -1pp)

Source: Eurostat, HICP inflation rates 2004-2014, ec.europa.eu, own calculations

In 2004 we see that there are no inflation targets, since inflation targeting was adopted since 2005, until then, the strategy of monetary policy is targeting monetary aggregates, but the National Bank of Romania switched to this well-known strategy.

In 2005 and 2006 the inflation rate was close to the upper limit of the inflation target, and in 2007 was below the upper limit of the variation interval of 5%, registering an inflation rate of 4.9%. Since 2008 and continuing through 2011, the inflation rate was situated well above the upper target. In 2008 we can notice the biggest difference between targeted inflation and the actual value of the inflation rate. The upper limit of the variation was 4.8%, while the inflation rate recorded a value of 7.9%, 3.1 percentage points above target. These difference is explainable because the government back then had some new fiscal policies implemented, and one of them was increasing the Value Added Tax from 19% to 24%, a value that was kept until 2016, when it was lowered to 20% overall, but for some products it was lowered to 5 or 9 percentage point.

In 2009 there was a decrease in the inflation rate, with a difference of 2.3 percentage points from the previous year, registering an inflation rate of 5.6%. This disinflation did not last long because in 2010 the inflation rate increased from 5.6% to 6.1%, up 0.5 percentage points. This was the last time the inflation rate increased from year to year, from 2010 it started to decrease to within the range of variation.

Since 2011 until 2012, the inflation rate has suffered a decline steeper than usual, while from 2012 to 2013, the decrease was smoother, the difference being only 0.2 percentage points and the difference between 2013 and 2014 was quite high and in 2013 the inflation target is close to the upper end of the range, and in 2014 it reached its sweet spot.

After the crisis period it is observed that the inflation rate has values increasingly lower. This can be a problem in the future because it can lead to a drop in inflation to near 0 or below 0, reaching the deflationary stage, which will take another quarter to confirm that this is the new normal. In the period of economic expansion, falling prices represent a negative output, and it is understood as necessary to adopt pro-cyclical macroeconomic policies because prices would have to rise and once they grow, they will help production, wages and investments to grow, ie the national economy will reignite itself.

The analysis of the output gap (the gap of production/supply)

The paper has allocated an entire subchapter for the analysis of the output gap because this indicator helps us understand the side of the wave a country's on. If the country rides the wave, then we are in a booming period and the economy tends to overheat on the long run, meanwhile, if we are under the wave, in the water, then the economy is in a recession and isn't capable of creating momentum for sustainable growth, especially without any policy developed by the government towards the idea of obtaining economic growth.

The output gap represents the difference between actual GDP and potential GDP as a percentage of potential GDP (Gălățescu, et al., 2007). This indicator helps analyze Romania's macroeconomic stability and to analyze the output gap we used the potential GDP during the 2004-2014 timeframe.

Potential GDP represents the real GDP of the economy at its peak without developing inflationary pressures. Deviation of GDP is generated by supply and demand and if real GDP is less than potential GDP, the economy faces a recession delay. Otherwise, it is now an inflationary gap.

Table 4: The analysis of the output gap (the gap of production)

Year	Real GDP (billion RON)	Potential GDP (billion RON)	Output gap (% potential GDP)
2005	462.3941	444.3628	4.05
2006	499.6426	468.9186	6.55
2007	533.9368	500.3267	6.71
2008	579.1024	531.6207	8.93
2009	538.1782	539.7445	-0.29
2010	533.8811	547.3029	-2.45
2011	539.5204	555.0503	-2.79
2012	542.9787	565.0632	-3.90
2013	561.3848	573.4183	-2.09
2014	576.8614	584.4831	1.30

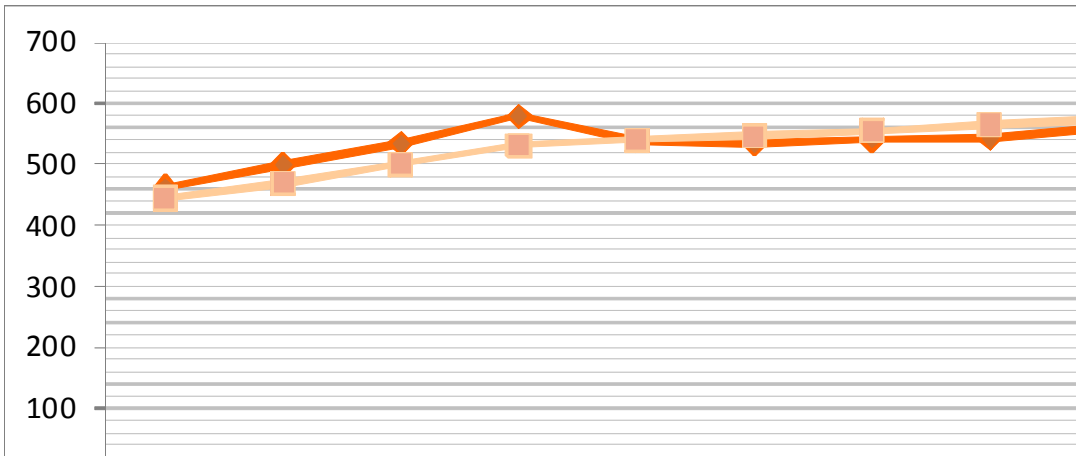

Fig 1. The evolution of real GDP and potential GDP in Romania's case

Real GDP / Potential GDP
Source: AMECO, ec.europa.eu

From this graph we see that in the period 2005-2008 Romania faced an inflationary gap because real GDP was higher than potential, while from 2009 until 2014 the balance intertwined and a recessionary gap could be seen, all because potential GDP was higher than actual (Belingher, Bodislav, 2014).

Inflationary gap is met if an expansionary economy is observed, when the economy evolves, you are more productive in your inputs and aggregate demand is greater than aggregate supply. If the recessionary gap occurs less than is needed in the economy, it will lead to a higher aggregate demand than supply aggregate.

The biggest difference between the potential and the real GDP was recorded in 2008, the difference being of 47.4817 billion lei. Since 2005 the difference between real GDP and actual GDP has been increasingly bigger and the gap got deeper. An expansionary economy may be characterized through the inflationary gap, which is observed in the case of Romania (Bodislav, Marinescu, 2011).

Due to the start of the period of crisis, and with its continuing recession, if there was a change in potential GDP and in the real GDP, then this change would involve lowering real GDP due to the crisis and very low growth rate for the potential GDP.

Registered recessionary macroeconomic movements were seen since 2009 when the gap was small, but it deepened until 2012, starting to decline as from 2013. In 2012 the difference between potential GDP and the real one was 22.0845 billion lei (Belingher, Bodislav, 2014). Compared to 2009, this difference is significant for the Romanian economy, but since 2013 this difference has disappeared, dropping to 10.051 billion lei in 2013 and reaching 12.0335 billion lei in 2014.

In 2014 the recessionary gap is less visible than in previous years, real GDP with a value of 576861.4 billion lei, while potential GDP was 584483.1 billion lei. The difference between the two indicators is 7.627 billion lei.

From the previous chart on the production gap of Romania there can be observed that when values are positive the inflationary gap is is motion and when it encounters negative values, then the economy is in a recessionary gap. As values are further from 0, the gap gets deeper. By gap analysis there could be determined what economic policy measures are needed for better functioning of the economy. Key economic policies are the policies used for the development of the macroeconomics side, such as monetary policy, fiscal policy and employment policies and by analyzing these policies there could be determined development needs and stabilizing the economy.

In the situation of an inflationary gap, the central bank through its monetary policy can cause inflation and can maintain under control the strong impact had on the economy. In case of the evolution of inflation, the central bank can intervene by adopting countercyclical measures to avoid creating a huge imbalance and destabilizing the inflationary pace of economic growth. The most used measures of monetary policy are closely related to the liquidity in the economy which can influence inflation. As there is more liquidity in circulation, so the inflation rate could rise because the purchasing power of money decreases, leading to a devaluation of the national currency. Liquidity can be controlled by the central bank through various monetary policy tools, such as open market operations, standing facilities granted to credit institutions, and required minimum reserves.

The recessionary gap was developed during 2009-2014 timeframe due to the negative effects of the crisis on key economic indicators. They suffered a sharp decline and have recovered due to tighten economic policy measures used by the government (Belingher, Bodislav, 2014). Although the difference between real GDP and the potential are decreasing, actually in 2015 the forecast is that the real GDP could have a small increase over the potential one, cyclical methods adopted by the government have failed to stabilize the economy or bring higher economic growth and faster, but the global economic contraction reduced the potential GDP towards the real GDP (Bodislav, Marinescu, 2011).

The measure of fiscal policy practiced in Romania after the period of crisis has had a big impact on the economy and had as workflow mechanism increasing state fees and taxes. By this measure it was influenced negatively the consumption of the population, which recorded a low level and aggregate demand sloped without recovering till today. By analyzing the output gap is observed the excess demand or supply on the market. During inflationary gap is seen as positive, which means an inflationary period in which aggregate demand is greater than aggregate demand (Gălățescu, et al., 2007). During 2005-2008 the gap had values increasingly higher, from 4.05% to 8.93% of potential GDP. In 2006 and 2007 it had a small increase of only 0.16 percentage points.

A big difference is observed between 2007 and 2008 when the gap increased from 6.71% to 8.93%, 2.22 percentage points. The crisis has had a huge impact on the demand difference between 2008 and 2009 creating a 9.22 percentage point gap in 2009 a negative value it that is noticeable on aggregate demand which has fallen below the level of supply and Romania went full frontal into recession.

Consumer's behavior – the disadvantaged entity

After joining the union, the movement of goods and services were accelerated, but also the Romanian people were motivated to travel freely around the European Union. The population could migrate to developed countries, while foreign investors invest in Romania and develop the country intensively. Investors have brought technology and know how from more developed countries, and this way they also developed and increased the quality of exported products and services. Import of technology has been very beneficial for Romania, through this process the employees were enlightened and increased their productivity.

Due to increased positive net exports and trade liberalization, but also due to higher quality products and cheaper labor than the rest of the union, Romania had to gain complementary benefits from being a full member of the European Union. In the case of developing countries, labor is cheaper than in developed ones and this can lead to an increase in foreign investments. Foreign investors invest and produce in Romania due to cheap labor, and export to other countries that are members of the EU. This helps Romania in terms of export growth, increasing foreign investment and increasing production, leading to sustainable economic growth and development.

Liberalization and EU membership had positive effects on the country and the population, as it has evolved at a faster pace compared to previous years, especially in terms of technology, by borrowing knowledge and qualitative development methods from countries more advanced both in terms of technology and economic.

After this period of expansion of the Romanian economy, in late 2008 the global economic crisis began and Romania was affected. Suddenly, everything started to fall, first were the banks and shortly followed by countries. The population began to consume less, so aggregate demand went South while aggregate supply couldn't be shifted because of the positive expectations had on the global economy till the crises. Due to declining consumption, production was affected almost at the same time and wages started to go South too, unemployment was increasing, and many firms went bankrupt due to large losses. During the crisis, people were frightened by these rapid declines and although their income per capita was decreasing, they decided to save more rather than consume, no longer having confidence in the national currency. Because of this, the currency has depreciated more, inflation was higher than usual. Drop in consumption was also due to the rising prices of goods and services, people being more careful about what purchases they made in order to save money for the latter, the negative expectations were altering their habits.

Consumption was falling, manufacturers have suffered from it in times of crisis because they were left with many unsold products, and recorded large losses, some going into bankruptcy. These losses were due to an artificial increase of production from pre-crisis period when the economy was starting to overheat, wanting to meet household demand, and to increase their profits. Since the crisis, the

population has consumed not that much, company earnings were down, they no longer had to pay their employees and what they had as a financial tool was to reduce salaries and lay off many employees to survive the crisis.

During this period, people have seen wages decline, but prices remained stable or even grew while trying to save as much to overcome the decline of the economy.

Banks were among the hardest hit by the crisis, because the population was no longer able to pay its debt, people remained unemployed and without an income to meet their obligations to creditors. Because of these issues regarding loans payment, banks have tried to find different fixes to the issues faced by customers, by increasing the credit period, the recovery plan acquittal or through various insurance schemes because some people were not able to cover their loans with personal possessions and also some companies have faced problems related to lending, due to lower revenues by lack of consumer spending, they were forced to grow products' prices and lower the number of employees through layoffs. Other companies entered bankruptcy due to large loans that were not paid and the goods with which they were covered weren't valuable enough to pay their debts. So some companies were left with huge debts and no income with which to cover.

During this period both the central bank and the state tried to take the best measures for overcoming the crisis. Thus, the central bank has reinforced the procedure through which they grant loans to lower the issues had in repaying loans and decreased the minimum reserve for commercial banks and increased its monetary policy interest rate. The central bank strengthened the credit granting system and let companies borrow if they could offer proof of assets and income that can cover loan.

The state, through the adoption of fiscal and budgetary policy measures, tried to stabilize the situation and help people to return to the pre-crisis financial state and state of mind. The government adopted pro-cyclical measures to cover the budget deficit and the public debt that was becoming increasingly larger.

The greatest impact on the population was the increase of the Value Added Tax from 19% to 24%, 5 percentage points. Thus, almost a quarter of the value of the purchased product came to the state to cover deficits caused by the crisis. The population did not anticipate the state's reaction because even though taxes were increased, people consumed increasingly less because their incomes have not increased in line with taxes.

Another measure adopted by the government was the 25% reduction of salaries for state employees. This would have been developed to cover part of the public debt and the budget deficit. This measure is pro-cyclical because it does not reduce wages to encourage people to consume so aggregate demand remained at a lower level compared to the aggregate supply. Meanwhile, there were staff restructuring, to cover losses and reduce expenditure necessary to it.

Conclusion

After the crisis, the Romanian economic situation has not changed much, remaining at almost the same gaps level. People got used to the fact that prices rose but their incomes remain the same or even decreased, they are more cautious in terms of how they spend their income today, but even more careful when they borrow, the risk of not reimbursing loans being higher than in the previous period.

To exit the recession and evolve economically, a country must stimulate the population to increase their consumption, foreign countries should import goods and services and the state should be more cautious in organizing public spending and eliminate deficits recorded during the crisis.

The population will only increase consumption if prices will drop for products or taxes will be reduced. This relaxation will give people more money to spend as available income and thus

confidence in the national currency will increase. Also, consumption will grow only with real wage growth, being in tune with the population's income. With higher incomes, people will have a tendency toward higher consumption and saving process will become increasingly smaller as a rate. Thus, by increasing consumption, the country's economy will be growing and economic deficits will tend to decrease, and the difference between potential GDP and the real will lower to almost zero. By increasing consumption production is encouraged, thus there will be an increase of companies that will take loans, but also they will hire new employees, so the unemployment rate will drop. Due to an increasing demand and an increasing supply the social, political and economical life will be encouraged to evolve again, reaching a level of economy growth and stabilization and maintain themselves sustainable.

To reach the economic growth rate necessary to overcome the recession there is needed a production level increasingly higher, managing to reach the new consumption levels. If production increases, companies will record profits. Thus they develop their business by hiring new people, but also by importing new and more advanced technology necessary for a better and easier operation and to adapt to customer needs.

Importing technology is increasingly important for the population as the population purchases products since for their specifications and manufacturing qualities. Thus, the technology has great support from the population, developing countries reach the level of developed countries at a faster pace.

In Romania's case a circular flow is inserted in the macroeconomic model because technological evolution is early adopted by Romanians and also this fact attracts foreign investors. By attracting foreign investors there are stimulated the development of communication channels with other countries, especially with those members of the European Union. Thus, exports will grow, but will also increase confidence of other countries worldwide in Romania's image seen through economic lenses.

Features of Optimal Control of Dynamic Processes in Enterprise Economics

Daniel S. Demidenko, Department of Finance, Institute of Industrial Economics and Management, Peter the Great St. Petersburg Polytechnic University, Russian Federation, demidenko11@rambler.ru

Ekaterina D. Malevskaia-Malevich, Department of Finance, Institute of Industrial Economics and Management, Peter the Great St. Petersburg Polytechnic University, Russian Federation, mmed11@yandex.ru

Abstract

The majority of processes in economic systems are dynamic, i.e. they are realized within several (more than one) periods of time. At the same time, in economic theory and generally in practice, as Braely and Myers (2004) mentioned they are described and studied as static processes which do not change in time, and, as a rule, their modeling does not consider a "time factor" variable, as in the book by Bellman (2013) is written. This can impede the optimality of solutions in economic management of real processes, and the time factor treatment is the most important in cash flows management and capital investment efficiency assessment as Forrester (1997) mentioned. The economic dynamics model given in the present article is an element of the cost approach to analysis and management at the enterprise. To describe innovation processes the team of authors suggest using Von Neumann's "economic dynamics model" (Von Neumann (1971)). There are no special methods for finding dynamic optimization models solutions, but the authors recommend to use the universal Lagrangian method, described by Lancaster (2012). The statement of the dynamic optimization problem suggested by the authors demonstrates that, depending on the sequence of redistributions at intermediate steps, there can be achieved different outcomes. It has been proved that the whole sequence of redistributions is important for finding the optimal (maximum) eventual outcome.

Keywords : Dynamic Processes in Economics. Enterprise Economics. Economic Dynamics Models.

Introduction

Novozhilov (1967) and Aghion & Howitt (2009) mentioned, that the main feature of economic management of dynamic processes and economic dynamics models to describe them, is determined by their "chain nature", i.e. the relationship between parameters or methods of control at each stage / time period and the preceding or subsequent stages, which must be taken into consideration. In a research study by Park et al (2005) economic optimization of a dynamic process requires achieving the optimal eventual outcome at the end of the last stage of the process, but when developing the optimal management decision it is necessary to consider the results of the previous stages as restrictions on management optimization problem by obtaining the eventual outcome (Mintzberg et al (2001), Rodionov et al (2014)).

Problem Statement and Research Objective

Let us investigate the optimization of a real dynamic process economic management through the example of the process consisting of three consecutive stages, implemented in three time periods. Let us assume that at the initial (zero) period some generalized index of the process effectiveness is equal to 1. Index of effectiveness can be represented by output or sales growth rates, or some other criterion based on the principle "the more - the better". If the required "corrective actions" are not carried out, the index of effectiveness decreases in an "evolutionary" way, and within the three considered periods successively takes on the following values: 0.9 after the first period; 0.8 after the second period; 0.7 after the third period. To assess the effectiveness of the process in a whole, a

multiplicative criterion can be used, i.e. the process effectiveness index which can be expressed by the product of effectiveness indexes at different stages. So, the process under consideration with its evolutionary development has the following resulting effectiveness, based on the effectiveness of its stages: 0.9*0.8*0.7=0.504. Let us suppose that each stage of the process management can include a corrective action which can compensate for the effectiveness' negative dynamics and to "raise" the effectiveness of a stage up to the initial level. Each corrective action requires some "costs", with their value at any stage to make 1. Efficient process control requires three cost units, but we can realistically assume that the costs limit for corrective actions, available at the enterprise, does not reach the desired value. The following figure represents the scheme characterizing the process management effectiveness.

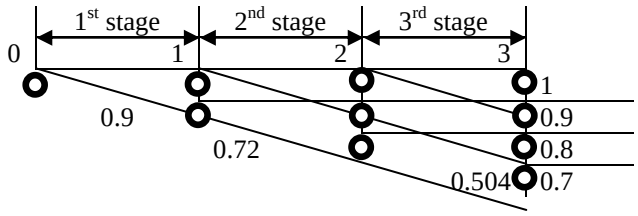

Fig 1.

The management strategy contains two alternative elements at each stage:

- implementing a corrective action, which corresponds to interruption of the evolutionary trajectory of the process effectiveness change (drop), requires control costs in the amount of 1 MU at each stage / step of the management process (horizontal line on the graph);
- lack of corrective actions (doing nothing, costs on control actions are equal to 0) and corresponding control costs (slanting line on the graph).

Based on the given conditions, the following task for optimal economic management of dynamic process is formulated:

$$\prod_{i=1}^{n} R_i(X_i) \to \max$$
$$\sum_{i=1}^{n} X_i \le L \quad ; X_i = \quad 0,1 \ \text{integers}$$

$$X_i = 0 - \text{doing nothing},$$
$$X_i = 1 - \text{control action},$$
$$R_i(X_i = 1) = R_{i-1}(X_{i-1})$$
$$R_i(X_i = 0) = R_i(X_{i-1})$$
$$i = 1...n$$

This optimization task is integer, nonlinear, with a multiplicative target function of effectiveness, which is given in a tabular form. To complete the task it is suggested to use the dynamic programming method. The numerical example is given in the full version of the article. Designations: $R_i(X_i) -$ value of function, specifying a process management effectiveness at the i[th] stage, in relation to the chosen control strategy X_i , L- management resource limit at the enterprise.

Let us designate the set of all integer managements cost values within the costs limits with "z": z=0,1…L, then we will have:

$$\varphi_1(z) = \max_{X_z}(R_1(X_z)), 0 \le X_z \le L, \quad X_z - \text{integer}$$

$$\varphi_i(z) = \max_{X_z}((R_z(X_z) * \varphi_{i-1}(L - X_z)), 0 \le X_z \le L, \quad X_z - \text{integer}, \quad i = 1...n$$

The problem is to be solved in stages, by using the above equations to calculate the "Bellman functions" -"φ", and the number of stages is equal to the number of periods (there are three periods in the given example). Any stage-to-stage distribution of management costs resources, other than the optimal one, provides less process management effectiveness.

The solution is made by steps, using the presented equalities to calculate the "Bellman function" "φ", the number of stages is equal to the number of periods, there are three periods in the given example. The solution is presented in the computation tables below. The first step involves calculating an unconditional optimum, the subsequent steps – a conditional optimum.

Table 1: 1st step/solution stage

$X_{1(\text{MU})}$	0	1	2
$R_1(X_1)$ (efficiency unit)	0.9	1	1

Table 2: 2nd solution stage

	2 stage					Max(1+2) stage
1 stage			0	1	2	
	0.9	0	$\frac{0.9*0.8}{0.72}$	$\frac{0.9*0.9}{0.81}$	$\frac{0.9*0.9}{0.81}$	0.72
	1	1	$\frac{1*0.9}{0.9}$	$\frac{1*1}{1}$		0.9
	1	2	$\frac{1*0.9}{0.9}$			1

Table 3: 3rd solution stage

	3 stage					Max(1+2+3) stages
1+2 stage			0	1	2	
	0.72	0			$\frac{0.72*0.72}{0.5184}$	
	0.9	1		$\frac{0.9*0.9}{0.81}$		
	1	2	$\frac{1*0.9}{0.9}$			0.9

On the first solution stage (Table 1) "Z" variable is sequentially "running" through all integer management cost values within the resource limit available (in the example L=2 MU), each resource value corresponds to the process management efficiency value attained in the context of these input requirements. This efficiency value will be optimal for the first process stage (due to lack of management alternatives).

On the second solution stage (Table 2) all integer values within the management costs resource limits are distributed among the process stages 1 and 2, and we select the management variant which provides maximum process management efficiency. The cells of the computation table 2 contain the values of the process management efficiency index. Each potential value of the residual management cost limit is represented by the computation table diagonal.

Thus, when distributing the residual management cost limit in the amount of 2 MU between the stages 1 and 2, if 1 MU is allocated for stage 1 and 1 MU – for stage 2, the process management efficiency equals to one, and in the context of multiplicative criterion for management efficiency the efficiency index for the two stages equals to the product of the stages' efficiency indexes 1*1=1. This is the maximum efficiency value at this diagonal. The rest of the table cells are filled in by analogy, and in the similar way the maximum management efficiency values at any other diagonal, corresponding to integer limit values, are determined. Maximum values of each diagonal are given in the last column of the computation table for stage 2, and it is transferred to the computation table for stage 3 which is filled in by analogy with Table 2.

The solution outcome is determined in the direction opposite to the solution course. As you can see from Table 3, the highest management efficiency amounting to 0.9 is achieved if the total management cost limit (2 MU) is allocated for stages 1 and 2, having nothing allocated for stage 3. As you can see from Table 2, distributing the limit between the processes 1 and 2 in equal parts is supposed to be optimal – the achieved management efficiency equals to 1 at stages 1 and 2. So, the total maximum available process management efficiency amounts to 0.9 (1^{st} stage – 1, 2^{nd} stage – 1, 3^{rd} stage – 0.9(1*1*0.9)). Loss of management efficiency in the amount of 0.1 is caused by insufficient management cost limit. As you can see from the management pattern, any other way of distributing management costs between the stages provides lower process management efficiency.

Key Results

The so-called "cost approach", as a method of financial and economic analysis and management at the enterprise, is currently widely used. In accordance with this approach, the main parameter of the enterprise's financial position, the criterion of its economic and financial management success is the market value of the enterprise (MVE). Herein, the MVE is defined by means of "returnable" cash flows capitalization from investments, and the outcome is evaluated on the principle "the more – the better". Cash flow reflects the economic dynamics of production process, the optimal management pattern corresponds to the optimal cash flow. If we speak about analytical optimization models, rather than about the econometric models based on statistical data, "Von Neumann's economic dynamics model" is supposed to be a traditional optimization model. So, the economic dynamics model is a part of the cost approach to evaluation and management at the enterprise. Let us take a detailed look at the model. Suppose within each period the enterprise uses "m" types of capital, aimed at different activities, with different efficiency. At the end of each period there can be a redistribution of capital types, and such a redistribution will become initial for the subsequent period. Types of capital can be represented by investment projects, as well as products. The eventual outcome depends on the way the benefits will be redistributed throughout several periods. Suppose there are m products available. The first index of any variable is a branch number, the second index is a period number. The process is being investigated throughout "n" periods. The outcome of each period is the "source material" for production in the subsequent period, provided that introducing new source materials and outside products, as well as their withdrawal are impossible.

Transformation of source materials into products can be expressed at each stage by a simple production function У=К*Х, where X is source material, Y is a product. Suppose X10 is the initial stock / capital of the first branch at the beginning of the 0 period, X20 is the capital of the second branch at the beginning of the 0 period. K1 and K2 are factors for branches / products (factors should not necessarily exceed 1, as investments in some branches can result in capital decumulation). Subsequently,

К1*Х10+ К2*Х20= У10 +У20,

where the right part suggests the "planned" allocation of capital by branch in the subsequent (1st) period, as Х11=У10, and Х21=У20.

The general scenario of dynamic optimization:

$$\sum_{i=1}^{m} K_i * Y_{ij} \rightarrow \max$$

$$\sum_{i=1}^{m} Y_{ij} = \sum_{i=1}^{m} K_i * Y_{i,j-1} = (*)_j$$

$$i = 1...m,\ j = 1...n$$

$$Y_{i0} = \sum_{i=1}^{m} K_i * X_{ij},\ X_{i0} - \text{initial conditions}$$

Let us consider the pattern of implementing the model represented in general terms when n=3:

$$(*)_3 = K_1 * Y_{13} + K_2 * Y_{23} \rightarrow \max$$

$$\text{with the restrictions:}$$

$$Y_{13} + Y_{23} = K_1 * Y_{12} + K_2 * Y_{22} = (*)_3$$

$$Y_{12} + Y_{22} = K_1 * Y_{11} + K_2 * Y_{21} = (*)_2$$

$$Y_{11} + Y_{21} = K_1 * Y_{10} + K_2 * Y_{20} = (*)_1$$

$$Y_{10} + Y_{20} = K_1 * X_{10} + K_2 * X_{20} = (*)_0$$

$$X_{10}, X_{20} - \text{initial conditions}$$

Suppose К1=2, К2=3.
Initial conditions Х10=10, Х20=10.
The Table represents 4 steps for two different distribution variants.
The columns (*) contain the results of formula evaluation (*)

Table 4: Computation Table 4

Period	Variant 1					Variant 2				
	Х1	Х2	(*)	У1	У2	Х1	Х2	(*)	У1	У2
0	10	10	50	20	30	10	10	50	30	20
1	20	30	130	100	30	30	20	120	60	60
2	100	30	290	100	190	60	60	300	150	150
3	100	190	770	70	700	150	150	750	150	600
4	70	700	**2240**			150	600	**2100**		

Depending on redistributions consecutive order at intermediate steps, different results can be achieved. In this case, the consecutive order of Variant 1 is supposed to be "more productive". Please note that the "best" intermediate result does not automatically provide the best result at the subsequent step. So, based on the results of the 3 steps, Variant 2 is more effective, but after that an erroneous decision was made. The whole redistributions sequence is very important for finding the optimal (maximum) eventual outcome. The model involves an elementary transformation function, and it can be much more difficult under time-dependence of transformation coefficients. As a result of solving the problem, there appears a "main line", i.e. an optimal solution for resources redeployment at each stage or in each period. So, in the considered example the main line will be linear due to a simple character of the production function, the solution at each stage will be in favor of the higher return on investment, as the factor for Product 2 exceeds (К1 < К2), in this case the

linear trajectory is optimal (the so-called “Neumann’s ray” is a half-line starting at the origin, as, under the conditions of the problem, only positive values of costs and benefits are considered – X and У). Then, the optimization model itself, which includes minimizing the “distance” between the actual main line and the optimal one, can be created. Solving this problem is particular for each individual case. The given example suggests a linear main line as a result of a simple production function, the solution at each stage will support the higher return on investments. Any minimum departure from the main line is determined as the “distance of the point from the line”. If the main line has a linear character, the optimal trajectory is non-linear, as the distance from the line can be expressed by a quadratic function. At the end of each period the “types” of capital can go through redistribution, which becomes the start point for the subsequent period. In addition to "types" of capital, investment projects, as well as products or production branches, can also be considered.

Transformation functions can be much more difficult if transformation factors depend on the volume transformed and the relationship between the branches, still it will be a time dependence of transformation coefficients.

Conclusion

The description of the proposed model demonstrates an “explosive” increase in the effect of initial investments. That is why von Neumann’s model is very useful to describe innovation processes. There is no special method for finding a solution, but you can use the universal Lagrangian method.

Another important factor to ensure projects effectiveness growth is risk coverage. It can include risk hedging, i.e. compensation for risk-related economic losses, or risks causes treatment in order to reduce risks probability. Hedging can not reduce the risks number, probability and frequency, but it provides compensation for economic losses, predominantly - from the interruption of economic processes. Risk hedging is ensured by means of reserve provision. This can lead to lower revenue, as investments in reserves are not as efficient as reserves in other assets. That is why losses due to creating reserves must not exceed risks losses. The number of risks, as well as their probability and frequency, can also be lowered by means of removing risks causes. On the one hand, growth in investments leads to an increase in enterprise’s sales, returnable cash flows, profit and profitability, and on the other hand, risks losses grow as well. It is expected that the investment project, which provides more benefits with more money invested, can make it possible that some part of the resources are directed to some conventional “risk reduction fund” to be spent on removing risk causes and reducing the possibility to lose a scheduled returnable cash flow of income from investments.

If a returnable cash flow value decreases due to risk reduction fund payments, and the probability of risk “non-occurrence” increases, it is possible to achieve the maximum value of the expected net discounted income.

The optimization model, which is described in the report, reflects a possible approach to keeping risks records for developing investment programs, and it is acceptable for both the enterprise and the economic system in a whole.

Acknowledgment

This research was supported/partially supported by Peter the Great Saint-Petersburg Polytechnic University. We thank our colleagues from Department of Finance, Institute of Industrial Economics and Management who provided insight and expertise that greatly assisted the research, although they may not agree with all of the conclusions of this paper. We thank Alexander E. Karlik for assistance with methodology and for comments that greatly improved the manuscript.

Abstract

This study is proposing a framework to perform business analytics for Small and Medium Enterprises (SMEs) in the form of a mobile application. The integration of business and information technology (IT) is encouraged in this study to enhance the business performance of SMEs in Malaysia. Development and implementation of a solution to integrate business and IT processes of SMEs, ease the business monitoring job, and improve the insight on the business performance in a fast manner for the decision makers are the main objective of this study. The business analytics framework is implemented in smart devices to provide visualization and analytics on business data.

Keywords: *business analytics framework; Small and Medium Enterprises (SME); visualization; analytics;*

1. Introduction

In current world of business, majority of the enterprises are known as SMEs. Malaysia's SME Corporation defines SME based on two category which as simplified as Table 1.

Table 1: Definition of SME based on operation's size by S. C. Malaysia (2015)

Enterprise / Sector		Small	Medium
Manufacture	Sales Turnover	RM 300,000 to RM 15 million	RM 15 million to RM50 million
	Employee (full-time)	5 to 75 people	75 to 200 people
Service / other (Example: mining, construction, agriculture and etc.)	Sales Turnover	RM 300,000 to RM 3 million	RM 3 million to RM20 million
	Employee (full-time)	5 to 30 people	30 to 75 people

In Malaysia, U. Malaysia (2002) mentioned that 70% of the owners of Small and Medium Enterprises (SMEs) are illiterate to Information Technology (IT). This phenomenon occur as majority of the SME are not using Management Information System (MIS) in the business's daily operation but keep remaining their traditional operation methodology. Strong management skill, extra time and effort allocation to the business are needed by SMEs' owner for improving and enhance their business performance. The SMEs' employees especially salespersons who are still using manual and traditional method are hard to check and monitor their sales. In year 2012, M. M. S. B. Waranpong Boonsiritomachai (2014) stated that growth of digital data was increase by 48% with 90% of unstructured information based on the survey done by International Data Corporation (IDC). This survey clearly shows that IT is being involved into the entrepreneurs' business but the entrepreneurs do not completely utilize the advantage of IT for the enhancement of their business. According to Hilgefort, I. (2010), cases such as loss of productivity, flawed

decision-making and reduced agility in marketplace are occurred among the SMEs owners due to the lack of related information and they keen to draw decisions based on their unpremeditated knowledge.

Technical skills and excessive time are needed to analyse and visualize the performance of business. Therefore, business analyst will be employed to handle the analytics and visualizing tasks by the SMEs that concern about their business' statistic. However, it will increase the cost of the business and cause the business performance not able to be improved easily as it required a long period of time to visualize and analyse the business performance of SMEs.

The mobility and flexibility of the owners or stakeholders of SME to keep track on the business performance is limited as most of the existing business analytic frameworks are developed as desktop-based web application. Owners of SMEs are required to allocate more time to undergo on-site business monitoring and perform their business performance analysis within a fixed interval. It is also not flexible to the SMEs owners who are not able to keep track on their business performance dynamically.

2. Literature Review

2.1 Business Intelligence (BI)

According to Chandler, N. (2011), Business Intelligence (BI) acts as "an umbrella term that spans the people, processes and applications or tools to organize information, enable access to it and analyse it to improve decisions-making and performance management". BI is used to display the required information in vary usable formats focusing at the efficiency of the processes and technologies where the information is supplied. Fig 1 shows the multiple phases of BI deployment which is proposed by System Application and Products (SAP).

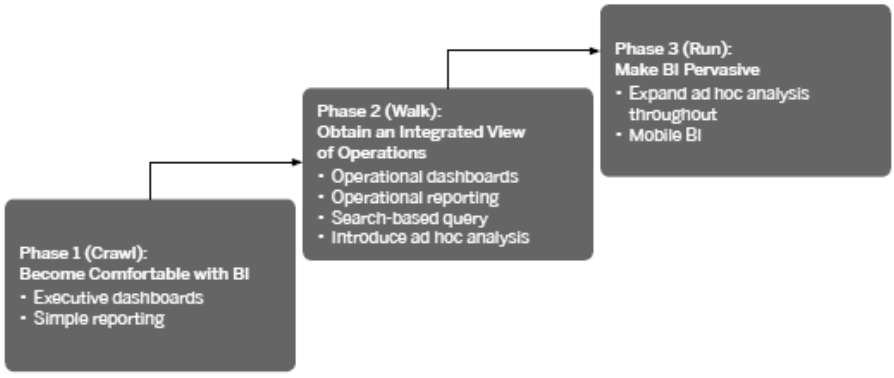

Fig 1. Phase by phase deployment of BI by SAP (2013)

2.2 Analytic Process

According to Hostmann, B. (2010), analytic applications are more focused by the enterprises rather than the analytics processes in midsize companies. There are five simple inquiry can be apply to enhance the analytics. The components of inquiry are as below:

- Things or knowledge that attempt to learn
- Method to measure success

- Methodology to design the process
- Type of analysis to be performed
- Data and data model to be used

These components are acting as a guideline for the analyst to determine the results for the overall process such as (i) to obtain a specific summary such as top best product; (ii) to relate the result to the business result such as accuracy estimation as the replacement for internal measures; (iii) to have a plan for each specific component analysis and; (iv) to decide the best model as well as the best data in analysis which mentioned by Hostmann, B. (2010).

2.3 Framework for Business Analytics

In the research study by SAP (2013), the Gartner framework defined the people, the processes and the platforms that are needed to be incorporate and regulated in taking a vital approach to BI. Business analytics framework also called as BI architecture. Rouse, M. (2015) mentioned BI architecture is a framework used to build BI system for data analytics and advanced reporting via technology components, data organization and information management.

There are a few aspects included in the general proposed framework solution. The aspects are as follows:

- Technology to integrate data from multiple sources
- Forming of system that support reporting and data visualization
- Complexity of analytics

Rouse, M. (2015) mentioned that various types of BI applications can be included in the framework such as data visualization tools, performance scorecards, dashboard, reporting tools, online analytical processing (OLAP) tools and data mining tools. In addition, comparing with other methods, the proposed framework has cross-functional capability in the use of information. Decision Data Model (DDM) and Data Availability Model (DAM) are the two main software product of Gartner's business analytics framework. However, DDM is the product which is used to construct the DAM. Fig 2 shows the DDM sample.

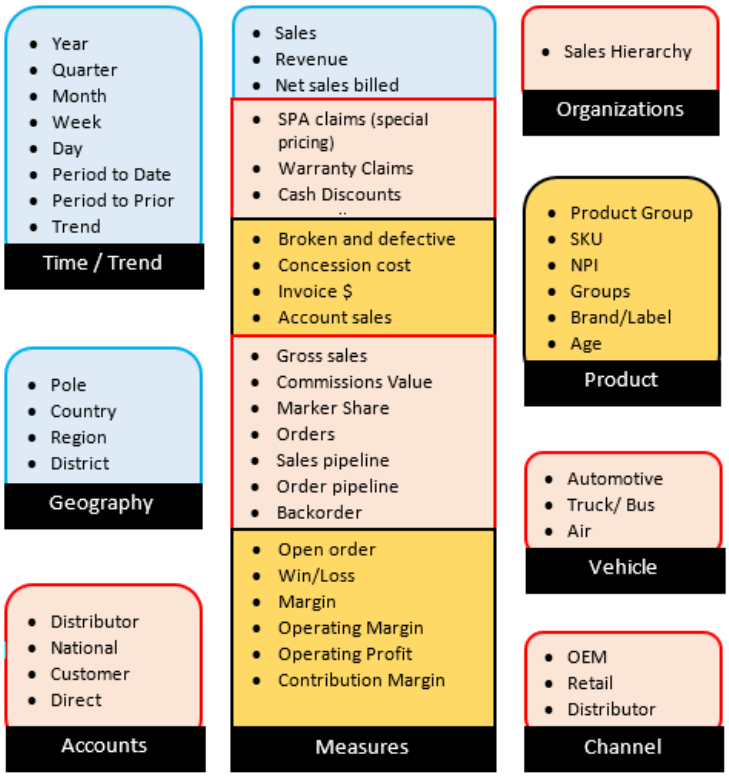

Fig 2. Decision Data Model (DDM) sample by Avalon Consulting, LLC., (2015)

2.4 Visualization of Data

This study aims to assist BI user to understand the importance of data by using visual context or data visualization. There are many data visualization software in the market to recognize trends and patterns as well as to ease the data correlations. BI dashboard is one of the data visualization tools to present the updated metrics and key performance indicators (KPIs). Rouse, M. (2015) mentioned that the main function of BI dashboard is to pull real-time data from various sources into custom-make interface.

3. Proposed Framework

In this section, the components of the proposed business analytic framework for SMEs will be discussed. The proposed framework contains five main components which are Data Collection, Data Processing, Data Loading, Data Analysis and Data Visualization. These components perform incrementally and finally a business solution can be developed as the output as shown in Fig 3. Each component will be discussed further in the following sections.

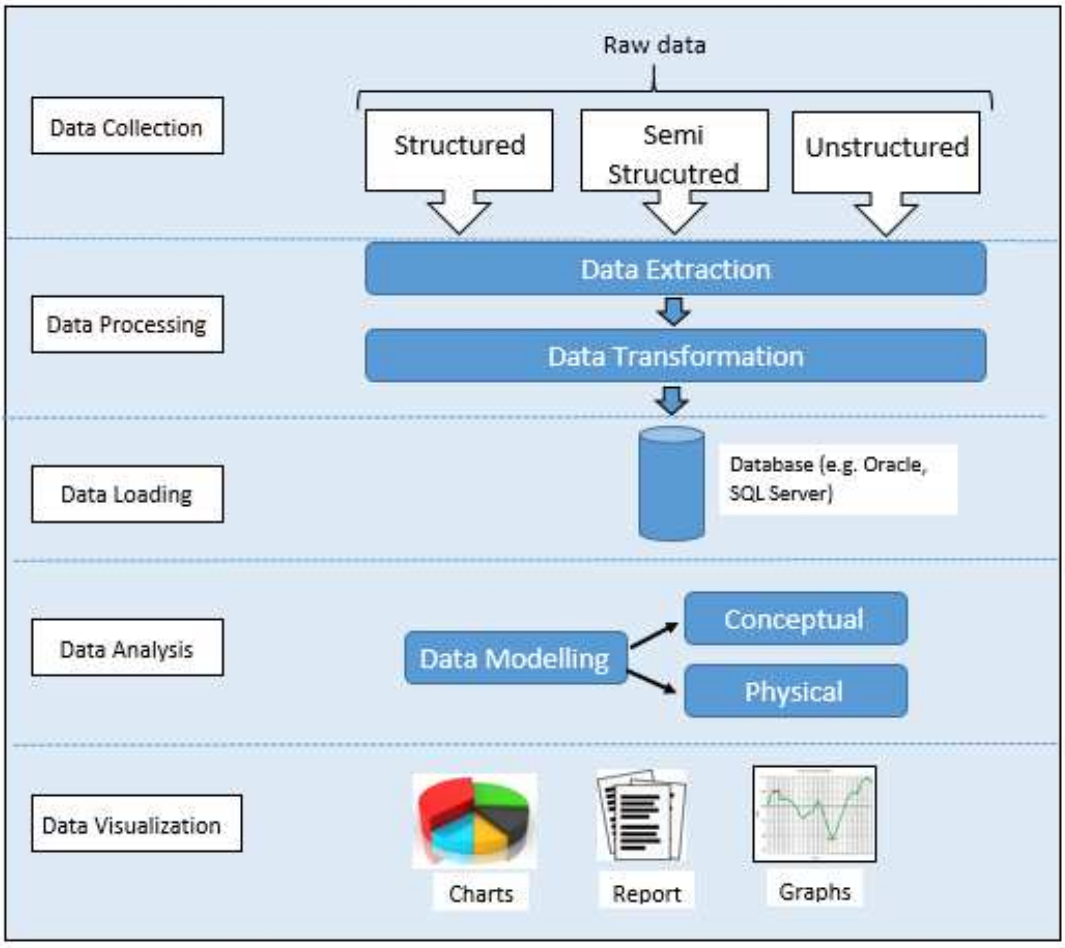

Fig 3. Proposed Business Analytic Framework for SME.

3.1 Data Collection

Data Collection is the first stage of the proposed business analytic framework. This is the stage where the data is being collected via different sources. The collected data is also known as raw data. Raw data can be categorized into three category. The three category are structured data, semi- structured data, and unstructured data. The data which are understood by the machine and ready to be used for processing are known as structured data, whereas semi-structured data are data which are not predefined but with a minor structure or formatting such as Microsoft Excel files (.xlsx), Unstructured data are the data which does not have any formatting such as text files and required more pre-processing as compared to structured and semi-structured data.

3.2 Data Processing

Data Processing is the stage after raw data has been collected from different sources. The two main processes that involve in this stage are the data extraction and data transformation. Data extraction is the process to obtain the required data from the sources for further processing. This extraction process can be performed by:

- Detecting and matching the text pattern of the raw data such as using regular expression
- Using text analytics techniques

After the extraction of data, cleanning process is needed to remove the unnessary data. Then the filtered data has to be loaded it into the staging database for the transformation of data. Data transformation is performed to reduce the skewness, standardized the data type and format of the collected data. This is to ensure that the data is usable and matched to the schema of target database or data warehouse in the next stage. Conversion of data type, application of business rules, validation of data and checking of data accuracy are involved in data transformation.

3.3 Data Loading

Data Loading is the stage where the processed data are being organized by loading it into the target data warehouse. The processed data are loaded and updated into the database periodically. The main concern in this stage is the efficiency and performance in order to ensure that the time required to complete the loading and update is optimized. The loading process can be executed in parallel to speed up the operation.

3.4 Data Analysis

Data Analysis is the most important stage in the framework where the data obtained from the past stages are being used to analysed according to the business requirements. Analysis of data is the important step for decision making and developement of ad hoc reporting, dynamic BI dashboard and other systems. Accurate results and meaningful information can be obtained by performing analysis on the collected data.

Analysis of data can be implemented by:

- Understanding the business requirements
- Designing the data model based on the requirements
- Designing the specification for the system
- Deciding the type of analysis that is suitable

The major component that involved in data analysis is data modeling. Data modeling can be divided into two sections which are the conceptual data model and physical data model. Both of the model are important for developing the system or application that is accurate and useful. Conceptual data model is the model that shows the scope of the system, organizing the requirement of data and designing the relationship between the data. Physical data model shows the design of the data in the database such as the data type and data contraints.

3.5 Data Visualization

Data Visualization is the stage where the analysed data is being presented using various tools. Visualization of data is to present the information in a more effective way which can provide an insight to the business users. The main aspects of creating good visualization for decision making are accuracy, clarity and uniqueness.

4. Implementation

The proposed framework is implemented by developing of a mobile application for an SME in the Android platform. A gas distributor business in Malaysia is adopted as the real business environment for the development of the mobile application by using the proposed framework. The data provided by the owner is the semi-structured data which is in Excel file. The data is extracted and processed according to the stages in the framework.

5. Conclusion

As a conclusion, the proposed business analytics framework is constructed for developing business analytics application or system for SMEs. This framework is designed to fit the SME's business which is smaller scale and do not involve complex business structure. It is to allow the owners and employees of SMEs to keep track on the business processes and performance easily. The management team such as SMEs owners can have a fast insight on their business by identifying problems in early stage and ultimately allow the management team to make a more accurate and insight decision. The SMEs owners and employees do not have to waste their time on performing business analysis using manual operation and able to keep track on their on sales records in an extensible manner. With the assistance of data visualization, the decision maker in SMEs can have a better perception or insight on their business and thus lead a better decision. Last but not least, the new and useful features that are implemented in this framework will surely enhance various parts of the business field.

Context of the Impact of Foreign Direct Investment on Residential Real Estate Prices in the Slovak Republic

Miroslav Panik, Institute of Management, Slovak University of Technology in Bratislava, Bratislava, Slovak Republic, miroslav_panik@stuba.sk

Julius Golej, Institute of Management, Slovak University of Technology in Bratislava, Bratislava, Slovak Republic, julius.golej@stuba.sk

Abstract

The article deals with the issue of the impact of foreign direct investment - notably car company Jaguar Land Rover on the prices of residential real estate in the vicinity of the implementation of major automobile plant in the Slovak town of Nitra. The investment was finally approved by the representatives of the plant in August 2015 and already in September of that year have become apparent different behavior in the market for residential real estate. Real estate prices until then are subjects to a prolonged stagnation. According to the theory, housing prices affect the volume of demand and supply factors affecting the real estate market. Despite that we know the main, specific factors and their impact, while foreign direct investment is not included among them, we can state that has its own considerable, especially psychological impact. This impact reflecting the current events in the property market in Nitra and its immediate surroundings.

Keywords: residential real estate, foreign direct investment, real estate prices, Slovak Republic.

Introduction

Automotive industry in Slovakia forms a significant part of the economy and attracts foreign investors. It is the driving force of economic development of the country. Based on this automotive industry Slovakia gained adjective "European Detroit" (Spirkova, 2015).

The automobile factory Jaguar Land Rover plans to invest in Slovakia about 1.5 billion euros, while the automaker since the beginning of its operation will employ 2,800 people. It is the largest investment in Europe for the past seven years. Government approved subsidies for tangible and intangible assets for the car-maker of € 130 million, representing nine percent of the announced investments. Construction of the plant began in 2016, first produced cars should leave the factory in 2018 until 2019. In the first phase, the production of 150-thousand vehicles are expected. Gradually, the annual production capacity of the plant can be extended up to 300-thousand vehicles with the possibility to employ up to 4,000 people. In accordance with the company plans, the plant should have the capacity to produce three million cars in ten years. According to the Minister of Economy of the Slovak republic, the new investment of car company Jaguar Land Rover should create a total of up to 50 thousand jobs including all subcontractors and all linked activities.

Slovakia has offered to car manufacturer 1,810 acres of land near the town of Nitra, which is located only about 80 kilometres east from Bratislava (more Fig. 1). In addition to the main factory land they were offered even more plots designated for each car company suppliers in its immediate vicinity (see Fig. 2).

Fig. 1 City of Nitra in the context of Slovak Republic
Source: Authors, 2016

Fig. 2 Location of Jaguar Land Rover Automotive Plant
Source: aktuality.sk, 2015

Slovak towns and villages around other car factories have after the arrival of similar investors increased tax revenues, which are used for the renewal of buildings and infrastructure. There was reduced unemployment and the population increased. Building land and real estate become more expensive and municipalities are more attractive for developers but also for newcomers. One of the observed economic and social impact in the implementation of similar investments in Slovakia was the increase in residential real estate prices.

In addition to increasing employment in the region and in the neighborhood the company should also bring the improvement of road infrastructure in the surrounding villages. This will also

increase revenues from property taxes and from shared taxes, which can be used for development projects of villages.
New automobile factory Jaguar Land Rover in Nitra will most likely also employ the people from afar. Its location near the town of Trnava also shows that there will be fighting and the reimbursement of employees of near competitor PSA Peugeot Citroën (Fig. 1). According to Spirkova (Spirkova, 2015) this strategic investment realized by the French group in 2007 reached approximately 1 billion EUR.

Problem identification

We presume that Jaguar Land Rover investment will have a major impact on several economic variables, among them is the price of real estate in Nitra and its surroundings. Housing prices in the Nitra region has long been the lowest in Slovakia. By the end of 2015, residential property prices fell in this region. In the second and third quarters prices decreased two times in a row by 8 € per square meter of living space. The last quarter actually declined by €23 representing a decrease of more than 4% over the previous quarter.

Data about housing prices are available for Nitra region as a whole (a database National Bank of Slovakia), which is relatively large, ranging from the city of Nove Zamky to the south of Topolcany. In remote villages, the expected investment is not reflected on the real estate prices. Slovak citizens are not usually willing to travel to work farther than 20-30 km. In addition, people in Slovakia are not willing to change the place of residence and to move within the country because of work, as is common in Western Europe or in the USA. However, property prices rose in the city of Nitra and a very close neighbourhood by more than 15%. Prices increased. Especially of older apartments but also the prices of building land. The increase in prices is also confirmed by actual information of Real Estate Agencies, which dispose immediate information about changes of supply and demand on the local housing market. We note that in Nitra is clearly seen the growth of a local real estate bubble.

Łaszek, Augustyniak, Widłak (2010, p. 19-24) describe the cause of the so-called real estate bubble as follows. Demand in the housing market is growing due to increased profitability from renting. Rapidly growing demand on the limited, short-term offer causes housing prices growth. The banking sector is able in a short time to accumulate a large amount of funds and offer them in the form of mortgage loans to finance even higher real estate prices. Speculative transactions based on the expected continuation of the upward trend in prices in the future, further increasing the price level of real estate and creates so-called real estate bubble. After the bursting of the bubble, price decreases and converges to the equilibrium price. However, this declines has a negative impact on the banking sector, as it significantly depreciates capital deposited in bank mortgages, causing problems of the entire banking sector, which is one of the cornerstones of the entire economy. The complications from the banking sector oftentimes also mean serious complications and losses for the entire economic system and the emergence of the economic crisis, argue Łaszek, Augustyniak and Widłak (2010).

Buying land under the new car plant, similarly as in the arrival of other investors in the automotive segment, again did not occurs to any problems. A certain group of businessmen came to information about the land which state will need and cheaply were bought from its owners. They bought them for a few cents per square meters and then it turned out that the same land is buying state for the automobile company approximately for 15 Euros per square meters.
The Table 1 below explains the increase in prices of building land in municipalities, in which came earlier investments of automotive companies - PSA Peugeot Citroën and KIA Motors.

Table 1 Price increase of land in areas affected by investments
Source: UPSVAR, Statistical Office of the Slovak Repiblic, automobile companies, municipalities, 2015

Increase in prices of building land in € / m2	on car companies arrival	in 2015
Teplicka nad Vahom	€15 - 20	€80 - 85
Nededza	€13 - 20	€60 - 75
Gbelany	€3 - 4	€70 - 80
Zavar	€15 - 20	€40 - 50

The theory of real estate prices

The understanding of the evolution of prices in the real estate market is very important for the analysis to macroeconomic indicators. Real estate prices are influenced by a number of demands and supply factors affecting the real estate market. Key factors include disposable income, gross domestic product, the volume of housing loans, the volume of construction production of residential buildings, the growth of population and number of households (Car, 2009). A significant influence also has national economic policy. Monetary policy affects short-term interest rates, which directly or indirectly affect long-term interest rates and inflation expectations, influencing developments in real estate prices. Fiscal policy affects real estate prices through taxes (Hilbers et al., 2008).

On the issue of housing are linked many others economic activities that have a significant impact on the development of gross domestic product. Hilbers et al. (2008) estimates that this share ranges between 5-10% of GDP. The development of real estate prices may have a significant effect on overall consumption and economic growth (European Central Bank, 2003). In the context of monetary stability, growth in house prices supports the growth of residential investments and household consumption, relating to the improvement in real estate. In case of credit financing, real estate is the main form of collateral for granted loans. Decline in property prices due to the reduced ability of borrowers to repay loans can greatly undermine the stability of the banking system and cause much macroeconomic problems (Car, 2006). However, the issue of real estate prices is much more complicated. On the perfect real estate market, real estate prices are fully determined by supply factors, such as real construction costs and land prices (Himmelberg, 2005). The perfect real estate market practically does not exist. Therefore it is necessary to look at the determinants that affect real estate prices.

Spirkova (2009) states that apartment prices are rising mainly due to a fast growing economy and income. The important role play speculations therefore expectations of growth in real estate prices in the future. However, in the long-term is valid that faster economic growth is also reflected on faster growth in real estate prices (Spirkova, 2009).

The real value of property is determined by factors of individual locations that are set by their real circumstances and they are the reasons for the differences in actual real estate price. The property value is determined in particular by: the design of the building, the technical condition of apartments, equipment of apartments, inner state and furnishings inside the building, accessories of properties, heating system, location of the apartment in the building, orientation to the cardinal points, achieving the revenue from properties (Spirkova, 2009).

Factors influencing the prices of residential real estate

Property prices on the real estate market affect the demand and supply for real estate. Supply and demand are influenced by many factors.

Špirková (2009), argues that the most important determinant of prices is economic growth, household income, interest rates and credit availability, demographic factors, taxes, grants and subsidies of the state, construction of new housing and speculation related to the expected growth in prices.

Ivanicka (2003), argues that the interest rate significantly affects the demand because with low interest rates, investors invests their funds in real estate. On the contrary, when the interest rate is high, then investors may invest funds into financial and capital products. Low interest rates helping reduce construction costs, thereby increasing profitability if there is sufficient demand, as reflected in the relatively high prices of real estate. Investors expecting the profit increase, they initiate new construction which increases supply and cause overall growth of residential real estate funds. Supply and demand further reflect the increase or decrease in the amount of non-residential buildings. If the vacancy rate is high, higher than 3% from the overall fund's property, then there is a drop in property prices. Conversely, if there is a lack of available spaces prices rise significantly, which represents an impulse to launch a new construction (Ivanicka, 2003).

Cutler, Poterba and Summers (1991) in their work based on the results of the regression analysis argues that in the US there is a strong statistically significant correlation between the level of real estate prices and demand for real estate for housing. Miles and Pillonca (2008, pp. 145-175) developed an economic model that explains the change in real income of the population and population growth influence the price level of real estate. They also quantified, the extent to which the expected return to real estate in the future affects the growth of property prices.

Vizek (2010) modelled the prices of residential properties in countries of Eastern and Western Europe by using econometric approach. He used models with correction member, so-called ECM models and co-integration analysis to examine the real estate prices in the short and long term. He analysed two groups of countries. The first group consisted of four post-transformation countries: Bulgaria, Croatia, Czech Republic and Estonia. The second group consisted of three developed countries: Ireland, Spain and the United Kingdom. Residential property prices were modelled separately for each country as a function of income, interest rates, loan terms, construction production and employment. Results of the analysis show that the long-term interest rates significantly determine the prices in both groups of countries. Revenue of the population significantly affects property prices only in the group of developed countries. In the short-term, in both groups, real estate prices reacted to the change in the volume of new construction production and also for the change in income, interest rates and credit conditions. The change of credit conditions significantly affects the real estate prices in post transformation countries. Generally, interest rates and income determined the development of residential property prices in all observed countries except Ireland. There was an abnormal development of real estate prices.

ECM models were used in the analysis of residential properties prices in Sweden and the UK also by Barot and Yang (2002). The series of prices from 1970 to 1998 they found that the long-term intake of the population as well significantly affects real estate prices in both countries and that the supply adapts to demand with some delay. The interest rate was a significant factor of both countries, but a little more importance showed in Sweden. They also found that residential property prices in Sweden directly affect the amount of the cumulative debt of the population. However, in the UK, this relationship has not been confirmed.

Egert and Mihaljek (2007) by using panel method DOLS analysed the main determinants of the residential property prices in eight transformation countries in Central and Eastern Europe (CEE) and in nineteen OECD countries. In both groups of the CEE and OECD, they confirmed the very strong relationship between GDP per capita and real estate prices and also a big influence real interest rates. They proved that the demographic factor have more significant impact in the CEE countries than in OECD countries. Property prices have increased from the growth of real wages in countries in which the quality of living was worse in the past. Dynamic increase in residential property prices was observed in the countries where there was a well-developed banking and non-banking sector.

Lee (2009) researched by using EGARCH models the volatility of real estate prices and determinants in eight cities of Australia. Result of his work was achieved on time series from 1987 to 2007. In several examined cities has been found that the volatility of real estate prices is caused by different economic factors. In its analysis, he describes many standard factors that affect the volatility of real estate prices, but places particular emphasis on inflation.

Botric and the DeVilla (2005) analysed the regional real estate markets in Croatia by using hedonistic price method. The method is based on the theory that the price of a particular product is derived from the group of useful characteristics, which brings this product to the consumer. They concluded that residential property prices are generally dependent on the following factors: disposable income, credit availability, regional economic activity, and unemployment rate and population mobility. They also pointed to such determinants of real estate prices, which are often neglected, such as regional differences in the labour market and regional disparities in income of the population.

Hilbers et al. (2008) states that the cost of the buyer in the purchase of housing significantly affect revenues respectively, the rent for the lease of real estate, taxes and subsidies from the state. An important factor that affects the demand for real estate is the demographic trend, namely population growth and trends in the number and size of households, affecting the demand for real estate. The offer of residential properties affects the availability and price of building land, construction costs and legislation. Offer is generally adjusted to demand with a delay caused by obtaining building permits, design and realization of construction. Offer may be affected by the lack of competition in the construction industry and inflexibility associated with the availability of special materials (Hilbers et al, 2008)

Real estate prices in different regions of the country are very often deviating from the equilibrium price determined by the income and population growth of the region. Individual segments of the country, such as provinces or districts may influence each other. Several authors have examined the spatial auto-correlation of real estate prices between regions within a country.

Analysis of factors affecting the prices of residential real estate in Slovakia

Housing prices are determined by the amount of demand and supply factors that operate on the real estate market. Car (2009, pp. 2-8) divides these factors as follows:

Demand factors:

- Economic – economic performance, purchasing power of population, income and household income, unemployment,

- Demographic – population, the number of economically active households, fertility, mortality, marriage rate, divorce rate, the need for housing,
- Political – state housing policy, state grants and subsidies,
- Credit-financial – savings, rate of credit availability, interest rates, credit conditions, the rate of credit burden, the riskiness of loans.

Supply factors:

- Territory – a place of housing construction in land-use plans for towns and villages, the availability of building land for housing construction,
- Economic-Technological – the amount of capital invested in housing construction, the share of housing construction on construction production, the number of started apartments, the number of completed apartments, the number of apartments under construction, apartments disposals,
- Legislative and legal – legislative availability and support of housing construction.

Selection of the most important factors affecting the prices of residential real estate in the Slovak Republic and construction of the model

Among all defined demand and supply factors, Car (2009) selects those that most affect prices of residential real estate. For selection of these determinants were used the correlation analysis, which resulted in the selection of representative factors from groups of economic, demographic, political, credit and financial and economic-technical factors. According to Car (2009), the prices of residential real estate in the Slovak Republic the following factors are the most determined:

- GDP (economic factor),
- Average number of population aged from 25 to 44 years (demographic factor),
- The total volume of household loans (credit-financial factors),
- The volume of households loans for housing purchase (credit-financial factors),
- The volume of construction production of residential buildings (economic-technological factor).

The intensity of the dependence on the above factors and residential real estate prices is very high. Identifying of determinants is an important step towards completion of regression analysis, model construction and subsequent prognosis of the future, says Car (2009).

According to Panik (2014), based on the results of correlation and regression analysis, he mentioned as a key determinant of development of real estate prices:

- Population aged from 25 to 44 years,
- GDP
- Interest rates on loans granted to households.

Development of residential real estate prices in Slovakia and city of Nitra and related economic determinants

Development of average prices of residential real estate in the Slovak Republic since the first quarter of 2005 to the fourth quarter of 2015 is shown in Figure 3.

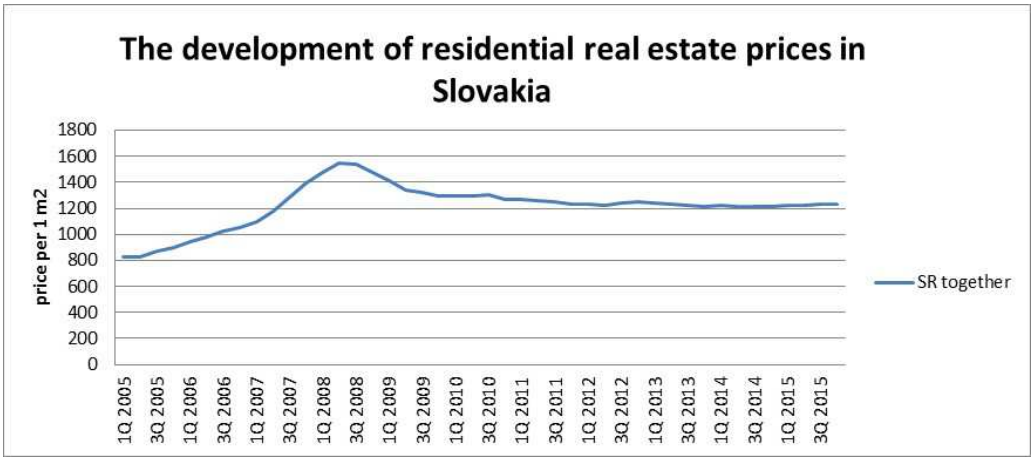

Fig. 3 Development of average prices per m2 of residential real estate in Slovakia
Source: Authors

Real estate prices in Slovakia rose slightly from the first quarter of 2005 to the third quarter of 2007. This increase is generally attributed to the positive expectations of foreign investors, mainly arising from the accession of Slovakia to the European Union in 2004. However, in late 2007 could be observed extreme increase in prices, which peaked in mid 2008. This phase is referred to as the real estate bubble, which is associated with various distortions of the real estate market, e.g. equal and many times higher price of older apartments as new buildings.

At the end of 2008 was a turning point in the evolution of prices. Due to the global mortgage crisis and overall economic recession, there was a bursting of real estate bubble and subsequent sharp decline in property prices which slowed down at the end of 2009. In 2010, prices have stagnated on the level of prices from 2007. From 2010 until now, the price trends are approximately a constant sometimes slightly decreases, sometimes slightly increases.

The average price of housing are now little above its long-term average €1,217 per m2 and corresponds to about half the level of 2007. The increase in average housing prices in the half of Slovak regions resulted in slowing improvement in housing affordability. However, housing is relatively the most affordable in the modern era of Slovakia (Car, 2015). Overall, it may be said that the residential real estate market in Slovakia recorded in 2015 a slow, but stable expansion.

Regional disparity in residential real estate prices

Residential real estate prices in Slovakia are strongly differentiated by regions. The most significant difference between the prices is in the Bratislava region and other regions. The decline in prices in 2009 is the most evident precisely in Bratislava (capital city) and Trnava (PSA Peugeot Citroën) regions, while the smallest decrease was recorded in the Zilina region (KIA Motors). The price development by regions is shown in Figure 4.

Fig. 4 The development of residential real estate prices in Slovakia by regions
Source: Authors

Follows from the foregoing that the Nitra region has the lowest average prices per one m2 of residential properties in Slovakia.

Impact of investment - Jaguar Land Rover on housing prices in Nitra and its surroundings

Notice about Jaguar Land Rover investment came in August 2015 and already in September was recorded the first wave of growth in real estate prices. One-room, not renewed apartment, which costs €44,000 increased to €55,000. Prices increased mainly in older apartments.

The arrival of Jaguar Land Rover has caused a significant increase in prices of residential property in Nitra and its surroundings. According to real estate agents, the apartments and houses in the region are sold by 20% more expensive than a few months ago. The arrival of a new automobile company initiated into Nitra a small local real estate psychosis, states Hudzovicova (2015).

Within a few months, after the initial information came that Jaguar Land Rover invests in Nitra region, housing prices has increased rapidly. Investors immediately expressed their interest in the construction of houses in the surroundings and immediately after the notification of the investment they were interested in the vacant building land (Brtka, 2015). Selection of cases which shows an increase in prices of residential real estate is documented in Table 2.

Table 2 Real estate bubble in Nitra
Source: SME, 2015

Type of appartment	prices in September 2015	prices in December 2015
1 room appartment	€44,000	€52,000
2 room appartment	€54,000	€60,000
3 room appartment	€55,000	€65,000

People from the city of Nitra and its surroundings will come to work to the new car company, unemployment will decrease and these workers will need someplace to live. It is already seeing an increased demand for real estate which, based on the above-mentioned economic theory will inevitably increase housing prices. In Nitra and nearby was created a small real estate bubble, which still will push prices up in a few months. Afterward, this bubble will burst. Real estate agents expect a subsequent prices decline from 4 to 7%. However, we estimate that the real decline will be even greater around 12-16%. Then the result would be a long-term increase in residential property prices by approximately 5%. This raises in new equilibrium price around which will probably the price converges in the future.

Currently are buying apartments or houses in Nitra only those people for whom it is convenient due to favorable bank loans or those who need as quickly as possible to resolve their living issues. Others prefer to wait.

Development of real estate prices in the Nitra region is shown in Figure 5. The figure shows the forecast according to real estate agents for 2016, i.e. prices increasing of 20%. An alternative forecast is pessimistic version, real (long-term) increase of housing prices by 5% to which authors are inclined like the more probable alternative.

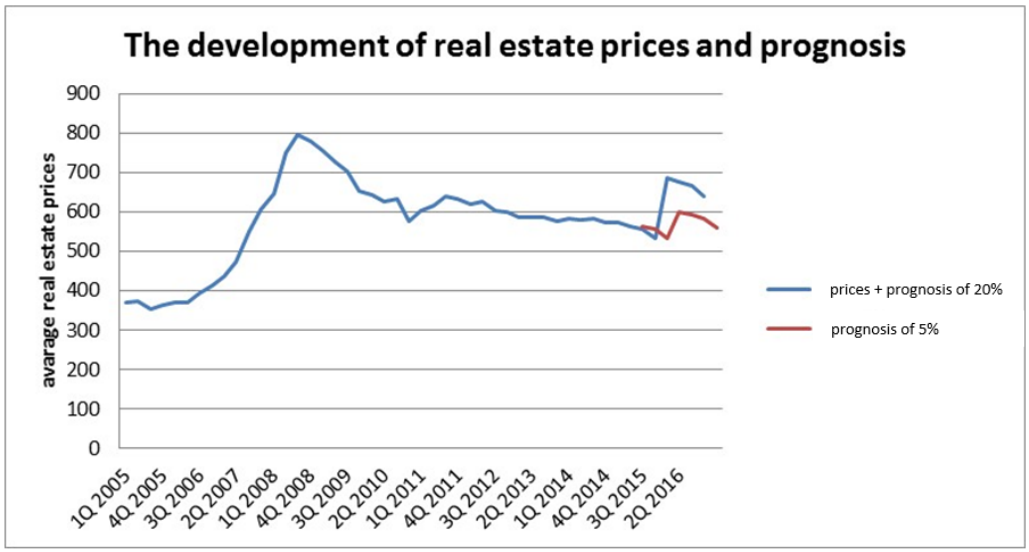

Fig. 5 Development of real estate prices and the prognosis in Nitra region
Source: Authors

Conclusion

Real estate prices in the Nitra region, in the long-term have stagnated and declining. However, now, after the arrival of new investment - Jaguar Land Rover, the level of residential real estate prices has moved upwards. This caused changes in consumer behaviour and increases the demand for housing, both for purchasing into private ownership or renting. We expect that the new equilibrium price will be increased by an average of 5% compared with the past.

Several authors have reported that the currently observe the increase in prices, up to 20%. However, they expect the equilibrium price on the edge of 13% of increase in the last year. In the city of Nitra is visible local real estate bubble, largely due to psychological effects and expected further growth of real estate prices. The main determinants of housing prices increasing in Nitra and neighbourhood is speculative behaviour of sellers who artificially raise real estate prices since they expect recovery in demand. This the demand is pushed by the expected growth of regional employment, and housing needs of newly employed workers of car company. Our findings are also consistent with practical experience in other regions of Slovakia, where after the arrival of similar investments were also observed a steady increase in residential real estate prices. In conclusion, we can say that, although the impact factor of foreign direct investment in the form of automobile company Jaguar Land Rover on housing prices in Nitra is not consistent with theoretical economic concepts of real estate prices. Furthermore by using statistical and mathematical methods it cannot be clearly demonstrating its dependency. However, it is necessary to add that this investment definitely has a psychological, and speculative impact on real estate prices in this area.

Resumen

El liderazgo educativo es uno de los factores clave para el desarrollo de una educación de calidad. Basado en una exhaustiva revisión bibliográfica, nuestro estudio explica la evolución de los principales modelos de liderazgo Se revisan las aportaciones más significativas y se destaca el modelo de liderazgo pro-social como forma de superar las limitaciones de otros modelos transformacionales y mejorar la gobernanza de las organizaciones educativas. Se concluye señalando la enorme vitalidad del liderazgo educativo en las últimas décadas y su capacidad de asimilar las virtudes de los diferentes modelos y erradicar sus limitaciones. Proponemos ahondar en el modelo de liderazgo trascendente para mejorar las instituciones educativas, tal como algunos académicos están realizando.

Palabras clave: liderazgo educativo; liderazgo transformacional; liderazgo pro-social; liderazgo distribuido

Abstract

Educational leadership is one of the key factors for the development of a high quality education. Based on an extensive review of the literature, our study explains the evolution of the principal models of leadership. The most significant contributions are reviewed and the prosocial leadership model is highlighted as a way to overcome the limitations of other transformational leadership models. We conclude by noting the enormous vitality of educational leadership in recent decades and its ability to assimilate the virtues of different models and eradicate its limitations. We propose to deepen the study of a transcendent leadership model to improve educational institutions, as some academics are already doing.

Keywords: educational leadership; transformational leadership; transcendental leadership; distributed leadership

Introducción

Las últimas investigaciones muestran que el liderazgo educativo es uno de los factores clave para el desarrollo de una educación de calidad y que existe relación entre liderazgo y resultados escolares, (Day et al., 2010; Hallinger y Huber, 2012; Harris et al. 2003; Louis, et al., 2004; Marzano et al., 2005; Mulford, 2013; Robinson, 2007; Robinson et al., 2008 y 2009). En este sentido, analizar los últimos estudios y conceptos clave relacionados con los principales modelos de liderazgo resulta indispensable para entender y emprender la organización y dirección escolar.

Por este motivo, con este trabajo pretendemos: en primer lugar, explicar la evolución de los principales modelos de liderazgo a lo largo de los siglos XX y XXI para extraer tendencias y mostrar caminos. A la vez, intentaremos dar respuesta a alguno de los muchos dilemas que surgen en torno al tema. El artículo revisa la bibliografía en torno a los modelos de liderazgo, explica sus ventajas y limitaciones y se detiene en considerar las aportaciones de varios autores, al modelo de liderazgo más extendido en la actualidad: el liderazgo transformador. Estos autores amplían el modelo con su propuesta de liderazgo transformador pro-social.

En segundo lugar, nos proponemos relacionar los modelos de liderazgo nacidos en el ámbito político y económico con los modelos del ámbito del liderazgo educativo. La investigación sobre liderazgo educativo ha seguido un camino muy parecido al de la investigación general sobre liderazgo, con algunas particularidades que la distinguen, y ha mostrado en las dos últimas décadas una enorme vitalidad no exenta de controversias.

En la actualidad, el liderazgo educativo adopta rasgos del liderazgo instructivo, el distribuido y el transformador en su sentido más contributivo (liderazgo transformador trascendente o pro-social). A este nuevo modelo de liderazgo se ha llegado a través de una historia a veces tortuosa llena de avances y retrocesos que explicaremos en las páginas que siguen. Nuestra propuesta es partir de este nuevo modelo de liderazgo para la transformación de las organizaciones educativas del siglo XXI.

Estado de la cuestión sobre los principales modelos de liderazgo en los siglos XX y XXI

Después de siglos de teorías que giraban en torno a los grandes hombres y que consideraban que los líderes nacen y son diferentes a los demás hombres, la aparición del liderazgo relacional constituyó en los años setenta del pasado siglo una auténtica revolución pues supuso pasar de un modelo centrado en el líder a un modelo centrado en la relación de influencia entre líderes y seguidores. El liderazgo relacional puede ser de dos tipos según el tipo de relación que se establezca: transaccional y transformacional (Burns, 1978; Bass, 1985; y Bass y Avolio, 1994).

Tabla 1: Tipos de Liderazgo Relacional

	Tipos de L. Relacional	**Subtipos**
Liderazgo Relacional	Liderazgo Transaccional	
	Liderazgo Transformador	Liderazgo Transformador Carismático
		Liderazgo Transformador Trascendente o Pro-Social

En la relación transaccional ("yo te doy y tú me das") líderes y seguidores mercadean con servicios y trabajos generalmente en relaciones de ordeno y mando basadas en premios y castigos. Burns (1978) consideró que las relaciones anteriores estaban basadas en motivaciones muy básicas y los seguidores no resultaban suficientemente tenidos en cuenta. Las teorías de Burns, que nacieron en el ámbito de la ciencia política, fueron adoptadas rápidamente y con gran éxito en el mundo empresarial a partir de Bass y Avolio. Sin embargo, las opiniones de uno y otros difieren en cierto sentido: Burns insiste sobre todo en el cambio social significativo (*significant social change*). Bass y Avolio están más preocupados por la consecución de los objetivos de una organización (*performance beyond expectations*). El tipo de líder que describe Bass tiene entre sus atributos principales el de la influencia carismática (influencia idealizada), motivo por el cual el liderazgo transformacional sufrirá años más tarde gran cantidad de críticas tanto a nivel empresarial como, sobre todo, a nivel educativo (Chirichell, 1999; Allix, 2000; López Yáñez, 2012; Northouse, 2007; Tourish, 2008; Bryman, 2004; Bottery, 2004; Gronn, 2000; Osterloch y Frey, 2003; y Sison, 2008).

El problema del liderazgo transformador es que resulta difícil distinguir cuándo una relación está motivada sólo por el atractivo de la tarea y la consecución de resultados para la organización, y cuándo lo que motiva la relación son las ganas que tienen los individuos de contribuir al bien de la sociedad o de la organización. Por este motivo, existe un grupo cada vez más numeroso de académicos que proponen un nuevo tipo de liderazgo transformador con diferentes ópticas. Estos nuevos modelos se denominan liderazgo trascendente, pro-social, altruista, transformativo, contributivo o antropológico (Bush y Glover, 2014; De Vries et al., 2010; Foster, 1986; Gardiner, 2006 y 2009; Grant, 2008 y 2013; Pérez López, 1996; Osterloch y Frey, 2003; Shields, 2010, 2014; Sison, 2008; Tintoré y Arbós, 2010 y 2012; Tintoré y Güell, 2015). Todos estos nuevos modelos comparten el deseo de ir más allá de las aspiraciones y necesidades del líder para intentar beneficiar a otras personas, organizaciones y sociedades.

Conseguir organizaciones de este tipo resulta difícil pero a la larga compensa pues el liderazgo trascendente genera unidad, lealtad y confianza. Todos ellos son elementos que aseguran "a priori" larga vida a una institución y una mejora en la situación de las personas que en ella trabajan.

En torno al cambio de milenio surgen nuevos modelos de liderazgo, muchos de los cuales serán propuestas perecederas. Sin embargo, en ese mismo momento, surge con fuerza el liderazgo distribuido, modelo que tuvo especial éxito en el ámbito educativo y el más duradero entre los liderazgos del nuevo milenio. Entre sus principales autores destacan Gronn (2002); Timperlay, (2005); Spillane (2005 y 2006), Halverson, o Diamond (Spillane, Halverson y Diamond, 2004).

El liderazgo distribuido se asocia al reparto de tareas (EPNoSL, 2013: 21) pero es más que eso: el verdadero liderazgo distribuido está relacionado con la implicación, y el compromiso de las personas de la organización.

La distribución del liderazgo es un elemento que crea capacidades en distintos lugares de la organización y puede contribuir a crear comunidad, cambio y efectividad (Day y Sammons, 2013: 35) pero el liderazgo distribuido, en nuestra opinión, no ha de considerarse como un modelo sino como una característica fundamental que ha de definir cualquier modelo de liderazgo para lograr una mayor eficacia y efectividad en las organizaciones.

Desde nuestro punto de vista, la gran contribución del liderazgo distribuido a la teoría general del liderazgo es que la difusión de este concepto ayuda a que el liderazgo deje de ser considerado como una característica individual y se considere una propiedad compartida dentro de un grupo de individuos (Aime et al., 2014; Spillane, 2006). Desde la aparición del constructo está más claro que nunca que "el liderazgo no es cuestión de rango ni un asunto individual" (Haimowitz, 2014).

Estado de la cuestión sobre los principales modelos de liderazgo educativo hasta 2010

La investigación sobre el liderazgo educativo comienza a desarrollarse con fuerza y de forma más autónoma entre las décadas de los 60 y 70 del pasado siglo y bebe, inicialmente, de la investigación más general sobre liderazgo a la que ya hemos hecho referencia (Murillo, 2006).

Durante los años 80, se desarrolla el liderazgo instructivo ligado al movimiento de investigación sobre eficacia escolar que evidencia la importancia de la dirección para conseguir escuelas de calidad. En este modelo, los líderes trabajan muy centrados en la enseñanza-aprendizaje (Neumersky, 2013: 318) y la investigación se centra en los directores (Elmore, 2000; Hallinger, 2005; Spillane et al., 2003). En realidad parecía que el liderazgo instructivo fuese sólo propiedad de los directores (Neumerski, 2013: 318) y según Sammons et al. (1995: 17): "el resultado de este movimiento fue un listado de características de las escuelas eficaces entre las que destacaba el papel del director como líder instructivo dotado de grandes poderes".

Philip Hallinger fue uno de los principales impulsores del liderazgo instructivo en los años 80 del pasado siglo y su cuestionario para medir dicho liderazgo (PIMRS), constituye uno de los primeros ejemplos para evaluar a los líderes instructivos (Hallinger, 1982, 1990 y 2011). Junto a Ronald Heck, desarrolló exhaustivas investigaciones mostrando los efectos positivos de este tipo de liderazgo en los resultados de los alumnos (i.e. Hallinger y Heck, 1996 y 1998).

Sin embargo, el propio Hallinger (2007) manifestó las limitaciones del liderazgo instructivo al que considera un enfoque excesivamente jerárquico y centrado en el director. Por eso, a partir de los años 90 se concedió un interés mayoritario al liderazgo transformador, que surge ligado al Movimiento de Reestructuración Escolar (Leithwood, 1996).

Leithwood define el liderazgo transformador educativo como aquel que "facilita la redefinición de la misión y visión de las personas, una renovación de su compromiso y la reestructuración de sus sistemas para cumplir los objetivos propuestos" (Leithwood, 1992: 9).

El liderazgo transformacional en educación pretendía desarrollar motivaciones intrínsecas hacia el trabajo y hacia los resultados en lugar de centrarse en un mero intercambio. Ello requiere mejorar las condiciones organizativas para conseguir un mayor compromiso de las personas en pro de los objetivos de la organización (Leithwood y Sun, 2012: 388).

Por ello, el liderazgo transformacional se centra en crear capacidades más que en el control y la dirección; en entender las necesidades de los individuos y en procurar el desarrollo de las personas mediante una serie de prácticas: definir y comunicar la visión, entender y desarrollar a las personas, rediseñar la organización como una comunidad de aprendizaje (Leithwood, 1992); y mejorar el programa de enseñanza (Leithwood y Mascall, 2008). De ahí que, en su desarrollo, el liderazgo transformador acaba por incorporar el liderazgo instructivo.

Las investigaciones de Leithwood y las basadas en sus trabajos, muestran que el liderazgo transformador aumenta la capacidad de los profesores para producir buenos resultados en los alumnos (Mulford, 2008: 42).

Pero a pesar de ello, el liderazgo transformacional va a ser objeto de críticas por el exceso de poder de un súper-director carismático (Mulford, 2008: 43). Ello lleva a que la literatura académica reclame un líder transformador más pro-social (Bush y Glover, 2014:6; Gairín y Rodríguez-Gómez, 2014: 820; Shields, 2004, 2010 y 2014; Tintoré y Arbós, 2010 y 2012).

Como en las empresas, con el cambio de siglo empieza a hablarse en educación de la distribución del liderazgo. Varios motivos hacen necesario este tipo de liderazgo (Hallinger, 2007 y Pont et al., 2008): la consideración de que los directores no lo pueden hacer todo solos, el desarrollo de la noción de las escuelas como comunidades de aprendices con un director como aprendiz principal (Louis et al., 2013) y la necesidad de conseguir un liderazgo más sostenible (Hallinger, 2009: 13) el cuál sólo será posible si el liderazgo está distribuido.

Existen pocos estudios empíricos que relacionen la existencia de liderazgo distribuido y la mejora en el aprendizaje de los alumnos aunque algunos parecen prometedores (Marks y Printy, 2003). Sin embargo, la existencia de un liderazgo distribuido por la organización no ha de suponer la desaparición del papel y autoridad del director, pieza clave para facilitar la distribución del poder por la organización (Hopkins y Jackson, 2002; Frost, 2010). En palabras de este último: "Los directores han de crear las condiciones para que el liderazgo se distribuya" (2010:213). Por eso, en opinión de Bush y Glover (2014: 10), y de Frost (2008: 337; 2010: 209) este modelo está muy ligado al del liderazgo de los profesores (*teacher leadership*).

A pesar de sus indudables ventajas, esta propuesta está muy lejos de ser una realidad en los centros educativos y –como ya hemos dicho – el liderazgo distribuido debería ser una característica de cualquier modelo de liderazgo y no un modelo en sí mismo.

Más allá del 2010: Liderazgo para el aprendizaje y propuesta de liderazgo pro-social

En la última década asistimos al desarrollo de un nuevo modelo de liderazgo educativo que – con diferentes denominaciones – suma algunas de las características de los modelos ya citados.

El origen de este nuevo modelo está en estudios que revisan las investigaciones sobre liderazgo educativo entre 1985 y 2006 y muestran que el impacto del liderazgo instructivo sobre los resultados de los alumnos es considerablemente mayor que el del liderazgo transformacional (Robinson, 2007; Robinson et al., 2008; Robinson et al., 2009). Otros autores, (Hallinger, 2007) sostienen que las similitudes entre liderazgo instructivo y liderazgo transformador son mayores que las diferencias y tienen muchas cosas en común. De esta forma se empieza a hablar de un nuevo tipo de liderazgo con características de los anteriores y mucho más distribuido.

El nuevo modelo asume del liderazgo instructivo su versión más pedagógica y menos autoritaria y controladora, el liderazgo transformacional lo desarrolla en su versión menos carismática y más pro-social teniendo en cuenta las necesidades de líderes y colaboradores y buscando su desarrollo y la mejora de la sociedad; y del liderazgo distribuido y el liderazgo transformacional adopta el objetivo de crear en los centros educativos comunidades profesionales de aprendizaje.

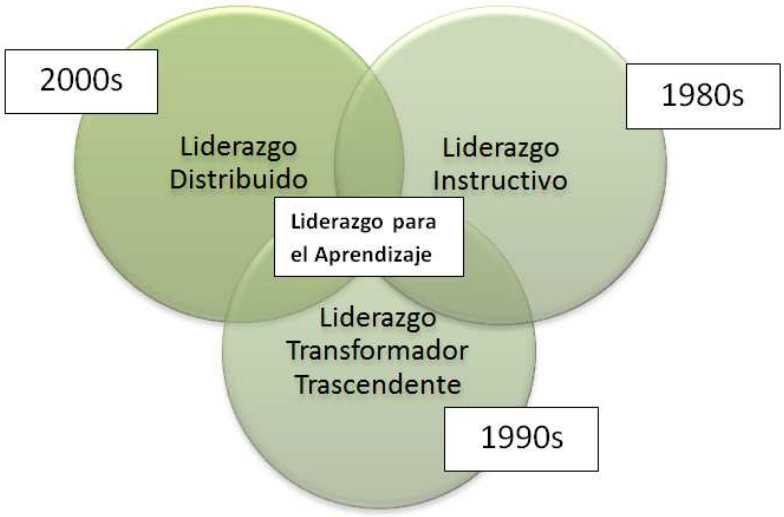

Fig 1: El nuevo modelo de Liderazgo educativo para el Aprendizaje

Este nuevo modelo muchas veces llamado "Liderazgo para el aprendizaje" y otras veces de nuevo "Liderazgo instructivo" rechaza que el director sea el único líder pedagógico de la escuela (Bush,

2013; Naicker et al., 2013; Mestry y Pillay, 2013: S1; Marks y Printy, 2003); sugiere el desarrollo de estructuras que favorezcan la distribución del poder (Mestry y Pillay, 2013: S2); considera que mejorar los resultados no consiste sólo en medir los resultados académicos de los alumnos sino en evaluar el desarrollo completo de dichos alumnos (Hirsh y Foster, 2013; Mulford, 2013) y por último integra características educativas basadas en concepciones del liderazgo instructivo, con otras características de los modelos transformacionales que mejoran la cultura de la escuela (Hallinger, 2003; Leithwood et al., 2002 y 2009; Robinson et al., 2008).

En un intento de crear sinergias entre todos los avances, pensamos que la propuesta de un liderazgo para el aprendizaje como el aquí descrito y que potencie las motivaciones trascendentes de los miembros de la organización daría respuestas a los interrogantes y polémicas a las que se enfrenta el liderazgo en el mundo educativo, de la misma forma que puede hacerlo en el ámbito empresarial.

Conclusiones

En el momento actual se está cerrando el círculo iniciado hace apenas cincuenta años. El liderazgo educativo, mostrando una gran vitalidad, ha sido capaz de incorporar las virtudes de los diferentes modelos de liderazgo desarrollados en la última mitad de siglo. Ha pasado de un liderazgo instructivo y autoritario a un liderazgo que vuelve a ser instruccional pero que adopta características más democráticas y se centra más en el aprendizaje que en la enseñanza (MacBeath y Dempster, 2009). El nuevo liderazgo supera el halo negativo que a veces envuelve al liderazgo transformacional cuando se centra en un líder carismático y visionario que resuelve todas las situaciones. Propone un liderazgo distribuido por todos los niveles de la organización escolar y también un liderazgo transformador con motivaciones pro-sociales en el que los miembros de la organización educativa trascienden sus propias necesidades en servicio de la comunidad. La preocupación por la mejora se ha extendido desde los resultados académicos a muchas otras facetas que pueden aprenderse. Y desde los alumnos a toda la comunidad educativa.

Siguiendo a Pérez López (1996, 1998), la adopción de un modelo de liderazgo de estas características debería permitir a las organizaciones educativas la consecución de un "óptimo de servicio" en el sentido de "hacer bien lo que la empresa ha de hacer y sabe hacer" (en el caso de las empresas educativas, educar). Y conseguir un "óptimo de desarrollo de las personas" contando con la libertad de las mismas, "porque sólo si las personas se desarrollan existirá la capacidad de lograr continuadamente los objetivos" educativos (Pérez López, 1998: 78) contribuyendo a la sostenibilidad del liderazgo.

Lograr estos objetivos y desarrollar este tipo de organizaciones no es tarea fácil pero puede hacerse. En otras investigaciones (Tintoré, 2014; Tintoré, Puig y Arbós, 2014) hemos mostrado algunos ejemplos de profesores y directivos líderes que han desarrollado y ayudado a desarrollar motivaciones extrínsecas, intrínsecas y pro-sociales en su trabajo. Líderes de muy diferentes zonas geográficas y en muy distintas posiciones que han sido capaces de ir más allá de sus propios intereses para ayudar a transformar sus organizaciones.

Existe casi unanimidad actualmente en que la principal tarea del director-líder es promover el aprendizaje de los alumnos a través de sus profesores (Bush, 2007; Southworth, 2002; Jenkins, 2009; Muijs, 2010; Hallinger y Heck, 1998; Muijs, Harris y Crawford, 2004. Citados por Glover, 2013: S179-80). A nuestro entender, eso está bien pero es el mínimo al que hay que aspirar. Centrarse en los resultados es necesario pero escaso, el liderazgo distribuido por la organización ha de encaminarse a conseguir el desarrollo de toda la persona y de todas las personas (alumnos, familias, profesionales, comunidad cercana).

Para conseguir un modelo de liderazgo que sea a la vez instruccional, transformador, pro-social y distribuido, los líderes han de crear las condiciones adecuadas en la organización: ha de existir visión y objetivos, una cultura de colaboración y confianza centrada en la enseñanza-aprendizaje, y estructuras que faciliten todo lo anterior y permitan llegar a constituir auténticas comunidades profesionales de aprendizaje (Marzano et al., 2005; Leithwood et al., 2010; Day et al., 2010).

Este nuevo modelo de liderazgo ha de tomar en consideración lo que se hace en la dirección y en las aulas, o sea, las prácticas de liderazgo (Begley, 2003; Bell et al., 2003; Day et al., 2009; Hallinger 2003; Leithwood et al., 2004; Robinson et al., 2008; Southworth, 2002 y 2003); cómo se hace, es decir, las características y actitudes de los líderes (Crossan, Ganz y Seijts, 2008 y 2012; Day y Sammons, 2013; Hallinger, 2007; Peterson y Seligman, 2004), y también para qué y por qué se hace (motivación). Considerar no sólo las motivaciones extrínsecas e intrínsecas sino también pro-sociales permitirá desarrollar liderazgos efectivos que desarrollan a todos los que participan en el proceso (Bush y Glover, 2014; De Vries et al., 2010; Foster, 1986; Gardiner, 2006 y 2009; Grant, 2008 y 2013; Pérez López, 1996; Osterloch y Frey, 2003; Shields, 2010, 2014; Sison, 2008; Tintoré y Arbós, 2010 y 2012; Tintoré y Güell, 2015).

En estos momentos, con muy diversas denominaciones, parece existir consenso en cuanto a las características que debe tener el liderazgo educativo en nuestro siglo. Ha quedado claro que es necesario pero no suficiente el liderazgo instructivo. Sabemos que hay que perseguir los buenos resultados pero eso tampoco es suficiente pues a lo que ha de aspirar el liderazgo educativo actual es al desarrollo de las personas y comunidades. Por eso el liderazgo ha de ser a la vez instructivo, distribuido, transformador y pro-social, sin olvidar que su objetivo no son los resultados sino las personas: educar y formar personas, y crear comunidades de auténtico aprendizaje para todos (Day y Sammons, 2013; Hallinger, 2009; Leithwood et al., 2004; Robinson et al., 2008; Stoll et al., 2006).

Abstract

In our research we focus on consolidated groups of taxpayers, which had been implemented in the Russian Federation in 2012; on importance of taxes paid by consolidated groups of taxpayers and their correlation with economic growth parameters. The modeling of economic growth have demonstrated its statistically significant relation to the rate of profit tax paid by the consolidated groups of taxpayers. This allowed us to conclude about the key role of the CGTs for the economic development of Russia, which should be taken into account in reforming the institute of consolidated groups of taxpayers. The distribution of the profit tax revenue paid by the greatest companies may become a basis for modeling the CGT involvement threshold.

Keywords: consolidated groups of taxpayers, corporate profit tax, economic growth

Introduction

Taxation relations and the mechanisms of their functioning are the subject of many researches of economists (Dolgih, 2015: Chistyakova, 2015; Khaperskaya, 2015; Rumina, 2015), since namely the taxation relations together with the monetary and credit policy (Ivanov, 2015) embody the possibilities of state regulation of any economics. In 2012, the Russia had established the law «The Consolidated Groups of Taxpayers», which set up the norms and rules for the tax authority and the taxpayer – CGT participants.

The extensive discussion about the possibility to consolidate the tax liabilities in Russia had been ongoing since the beginning 2000th (Aktaev, 2015: Bannova, 2015). The necessity to form the state institute of the consolidated taxation was caused by the existence of the following reasons:

1) the necessity of more equitable distribution of profits tax revenues among the regions in the Russian Federation;
2) the increase of tax withdraw frequency on account of transfer pricing;
3) the business splitting with the purpose to change the routine taxation schemes (the simplified tax system, the payment of unified tax on the imputed income);
4) the desire of the greatest taxpayers to simplify the tax bookkeeping;

For large holding companies, the consolidated group of taxpayers is not only the opportunity to determine their liabilities for the profit tax for the whole group of companies and to distribute it fairly among the regional budgets, but also to avoid the burdensome procedures of paperwork and the possible audit problems relating to the transfer price control inside the country.

The CGT induced the greatest problems for the regional budgets with regard to their income. The occurred principally differing redistribution of the CGT tax revenues among the territories of Russia was inevitable under existing formula of the tax distribution base of CGT members among the

regions. The overall decrease of the profit, which the regional authorities also related to the creation of consolidated groups, as well as difficulties in forecasting the budget tax revenue of certain regions, also contributed to the situation. As a result, since 2015 the registration of new and completion of the operating CGT was stopped. This decision allowed the time to analyze their activity and impact on the budget income, as well as mapping out a further strategy with respect to such groups. However, the CGT expansion was stopped until 2018.
In discussing of perspectives for consolidated groups of taxpayers as key stakeholders are consider state in general, and regional budgets. In our opinion, in amending the CGT, it is important to consider the significance of the CGT-involved companies for the development of Russian economy.
The purpose of this article is a research of CGT impact on the economic growth, as well as importance of profit tax paid by the greatest Russian companies.

1. Methodology

To assess the rate of the CGT profit tax revenue and its relation to the economic growth, we used the correlation analysis:

the correlation coefficient, the graphic method of simple regression modelling, and the coefficient elasticity. Also, we have evaluated the equation parameters.

The linear correlation coefficient ranges from –1 to +1. The relation criteria of the variables (weak or strong (close)) were estimated using the Chaddock scale correlation:

$0.1 < r_{xy} < 0.3$: weak
$0.3 < r_{xy} < 0.5$: moderate
$0.5 < r_{xy} < 0.7$: evident
$0.7 < r_{xy} < 0.9$: strong
$0.9 < r_{xy} < 1$: extra strong

The graphic method is applied for visual presentation of relations between the studied economic indicators. For this purpose, the variables were plotted in the rectangular coordinate system, the coordinate axis being for the sampling results Y and the abscissa one – for the factorial characteristic X .
The relation between the resulting points and those of factorial characteristics is defined as the correlation field.
On the basis of the correlation, it is possible to draw the hypothesis (for the general population) that the relation between all possible X and Y values is of a linear character. The linear equation of the regression looks like $y(x) = bx + a$. An estimating equation of the regression looks like $y(x) = bx + a + Ɛi$,
Here, Ɛi is a random variable (deviation, disturbance).
The reasons causing the random variable:
1. Lack of important explicative variables in the regression model;
2. Aggregation of variables. For instance, a function of total consumption is an endeavor of common expression of the total decision of individuals about charge. This is only an approximation of different variables (indicators relations) having various parameters;
3. An incorrect description of the model structure;
4. An incorrect functional specification;
5. Errors of measurement.
6. Since the deviation Ɛi is random for every i^{-th} case , and since their extracted values are unknown, then:
1) Using the observations xi and yi, we can evaluate only the parameters α and β;
2) The evaluations of α and β in the regression model are the magnitudes a and b, respectively, which are random, since they are randomly sampled. To evaluate the parameters α and β, we applied the least square method. The least square method provides the best evaluations of the parameters of the regression equation (the most sustainable, efficient and unbiased). However, this occurs only in

the case, when the definite premise of the relatively random member (Ɛ) and the independent variable (x) are fulfilled.

To analyze the quality of regression parameters, we used the dispersion analysis, the control of residual autocorrelation and heteroscedasticity.

2. Impact of CGT on economic growth

The correlation between the profit tax of the involved CGT (RUR thousand) and the rate of economy growth have been analyzed (the GDP gain in comparison with previous year, in %). The data on the profit tax of the involved CGT were based on the assessments of Federal Tax Service of Russia; the definitions of main parameters were given by Rosstat, then it was pointed on diagram and regression was derived:

y (x)= 0.0482 x -20.582

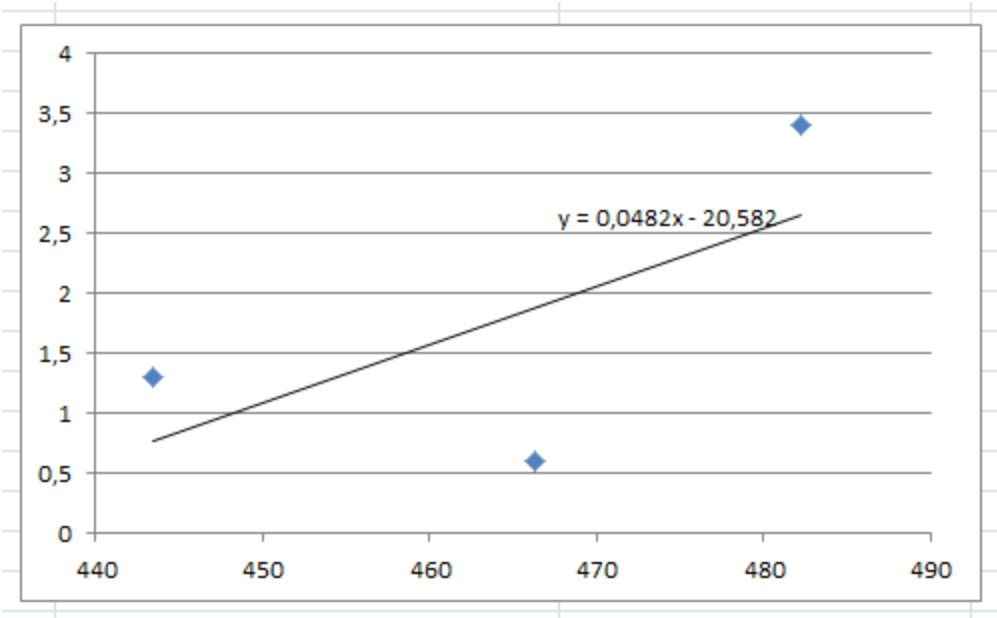

Figure 1 Graphical presentation of the empirical equation of regression

Regression equation (evaluation of regression equation)

The linear equation of regression looks like y(x) = 0.048 x-20.582
Thus, when the paid profit tax per RUR 1 thousand increases, the economic growth increases by 0,048

Correlation coefficient
The coefficient of linear correlation can be determined using the regression coefficient b:

$$r_{x,y} = b\frac{S(x)}{S(y)} = 0.048\frac{16.007}{1.19} = 0.645$$

Thus, the relation between the indicator Y and factor X is explicit and direct.
Elasticity coefficient

The average elasticity coefficient E indicates a percentage change of y indicator (the population mean) with respect to its average value if the factor x would change by 1% of its average value.
The coefficient of elasticity was found, using the following formula:

$$E = \frac{\partial yx}{\partial xy} = b\frac{\bar{x}}{y}$$

$$E = 0.048\frac{463.67}{1.77} = 12.59$$

In our example, the elasticity coefficient exceeded 1. Therefore, when X changes by 1%, Y would change by more than 1%. In other words, X significantly influences Y.

3. Evaluation of regression equation parameters.

Importance of correlation coefficient

Let us hypothsize:
H0: rxy = 0, there is no linear dependence between the variables;
H1: rxy ≠ 0, there is a linear dependence between variables;
To verify the null hypothesis about the equal-zero general correlation coefficient of the normal two-dimensional random variable under conditions of the competing hypothesis H1 ≠ 0, it is necessary to evaluate the sampled value (t_{nabl}) - a value of random error:

$$t_{nabl} = r_{xy}\frac{\sqrt{n-2}}{\sqrt{1-r_{xy}^2}}$$

and, using the table of critical points of a Student's t-distribution, a significance level α, and the number of degrees of freedom k = n – 2, to find a critical point of time (t_{kpum}) of bilateral critical area. If $t_{nabl} < t_{kpum}$, the null hypothesis cannot be rejected. If $|t_{nabl}| > t_{kpum}$, the null hypothesis is rejected.

$$t_{nabl} = 0.645\frac{\sqrt{1}}{\sqrt{1-0.645^2}} = 0.84$$

According to the Student's table, for significance level (value) α = 0.05 and k = 1 degrees of freedom, we find tkrit:
tkrit (n-m-1; α/2) = (1; 0.025) = 12.706
where m = 1 is a quantity of predictor variables.
If $|t_{nabl}| > t_{kpum}$, the obtained value of correlation coefficient is recognized as significant (the null hypothesis accepting the equal-zero correlation coefficient is rejected).
Since $|t_{nabl}| < t_{kpum}$, we can accept the hypothesis about the equal-zero correlation coefficient. In other words, the correlation coefficient statistically is insignificant. In paired linear regression $t^2_r = t^2_b$. Then, testing the hypotheses on the significance of regression and correlation coefficients is equivalent to the test of a hypothesis of the significance of regression linear equation.

Evaluation of correlation coefficient range (a confidence interval)

$$\left(r - t_{kpum}\sqrt{\frac{1-r^2}{n-2}}; r + t_{kpum}\sqrt{\frac{1-r^2}{n-2}}\right)$$

The confidence interval for the correlation coefficient

$$\left(0.645 - 12.702\sqrt{\frac{1-0.645^2}{3-2}}; 0{,}645 + 12{,}706\sqrt{\frac{1-0.645^2}{3-2}}\right)$$

r(-1;1)

Analysis of estimation accuracy of regression coefficient

The value

$$S^2 = \frac{\sum(y_i - y_x)^2}{n - m - 1}$$

$$S^2 = \frac{2.48}{1} = 2.478$$

is an unbiased estimation of the disturbance dispersion

$S^2 = 2.478$ is a non-predicted dispersion (the dispersion rate of dependent variable around the regression line)

$$S = \sqrt{S^2} = \sqrt{2.478} = 1.57$$

S = 1.57 is a standard error of evaluation (a standard regression error).

S_a – is a standard deviation of random value a.

$$S_a = S\frac{\sqrt{\sum x^2}}{nS(x)}$$

$$S_a = 1.57\frac{\sqrt{645729}}{3 * 16.007} = 26.34$$

S_b is a standard deviation of random value b.

$$S_b = \frac{S}{\sqrt{n}S(x)}$$

$$S_b = \frac{1.57}{\sqrt{3} * 16.007}$$

Confidence interval for dependent variable

The economic forecasting, which is based on the above model, assumes that earlier existing relations of variables remain for the predictor period. Forecasting the depending variable of promising indicator needs a knowledge of predictor values of all factors involved in the model. These predictor values are substituted into the model and points of the predictor values of the studied indicator are obtained.

$(a + bx_p \pm \varepsilon)$

Let calculate the interval space (range), in which 95% of acceptable Y values are under unlimited quantity of observation and Xp = 510.

$t_{крит}$ (n-m-1;α/2) = (1;0.025) = 12.706

y(Xp) = 0.048*510 -20.472 = 3.989

Let calculate the prediction error for the equation y(x) = bx + a

$$\epsilon = t_{kpum}S\sqrt{\frac{1}{n} + \frac{\left(\bar{x} - x_p\right)^2}{\sum(x_i - \bar{x})^2}}$$

$$\epsilon = 12.706 * 1.574\sqrt{\frac{1}{3} + \frac{(463.67 - 510)^2}{768.67}} = 35.368$$

or

$$\epsilon = 12.706 * 1.574\sqrt{\frac{1}{3} + \frac{(463.67-510)^2}{3(215243-463.667^2)}} = 35.3683.989 \pm 35.368$$

(-31.38;39.36)

The probability that Y would not be outside the scope predictor ranges under unlimited quantity of observations can reach 95%.

Let calculate the prediction error for the equation y = bx + a

$$\epsilon = 12.706 * 1.574\sqrt{1 + \frac{1}{3} + \frac{(463.67 - 510)^2}{768.67}} = 40.63$$

$(-36.64;44.62)$

4. Qualitative analysis of regression model

Dispersion analysis

Analyzing the quality of regression model, the theorem of dispersion factorization, according to which the general dispersion of indicator can be factorized into two components: one of them is the predictor of dispersion regression and another one is not.

The dispersion analysis is aimed at parsing the dependent variable dispersion:
$\sum(y_i - y_{cp})^2 = \sum(y(x) - y_{cp})^2 + \sum(y - y(x))^2$

Where

Ycp - marginal (means)
$\sum(y_i - y_{cp})^2$ - the total sum of squares of the deviations;
$\sum(y(x) - y_{cp})^2$ - the sum of squares of the deviations due to regression ("predicted" or "factorized");
$\sum(y - y(x))^2$ - the residual sum of squares of the deviations.

Source of variance	Sum of Squares	Degrees of freedom	Variance of 1 Degrees of freedom	Fisher's Exact Test
Model	1.77	1	1.77	0.71
Residual	2.48	1	2.48	1
Total	4.25	3-1		

Count Measures of quality regression equation

Count Measure	Value
R Square (R2)	0.42
Mean of the coefficient elasticity	12.59
Mean of the approximation error	91.87

Verification of existence of residuals autocorrelation

If the coefficient of autocorrelation $r_{ei} < 0.5$, we can reasonably affirm that the autocorrelation is absent.
To define a range of autocorrelation, let us calculate the coefficient of autocorrelation and verify its significance using by the standard error criterion. The standard error of correlation coefficient is calculated by the formula:

$$S_{eY} = \frac{1}{\sqrt{n}}$$

The autocorrelation coefficients of random sampling should possess the sampling distribution approximating to a normal with null population mean and mean square deviation being equal to

$$S_{eY} = \frac{1}{\sqrt{3}} = 0.577$$

If the autocorrelation coefficient of the first order r1 ranges within:
$-12.706 \cdot 0.577 < r_1 < 12.706 \cdot 0.577$
we can conclude (assume) that the data do not demonstrate the autocorrelation of the first order.
Using the estimation table, we obtain:

$$r_1 \approx \frac{\sum \epsilon_i \epsilon_{i-1}}{\sum \epsilon_i^2} = \frac{-0.275}{2.478} = -0.111$$

Since -7.336 < r_1 = -0.111 < 7.336, the dependent feature of residuals is fulfilled. There is no autocorrelation.

Durbin-Watson's criterion

This criterion is the well-known test allowing us to confirm the autocorrelation.
Usually, at an initial stage of statistical analysis of the regression equation, one predictor realizability is verified : conditions of statistical independence of deviations. At the same time, uncorrelated neighbor estimators ei are verified.
The Durbin-Watson's statistics allows us to analyze the deviation correlation:

$$DW = \frac{\sum (e_i - e_{i-1})^2}{\sum e_i^2}$$

$$DW = \frac{3.3}{2.48} = 1.33$$

The critical values d_1 and d_2 are defined using special tables of significance level α, the number of observations n = 3, and a quantity of predictor variables m = 1.
There is no autocorrelation, if the following condition is fulfilled:
d_1 < DW and d_2 < DW < 4 - d_2.

If 1.5 <dw <2.5, we can use a approximate rule and consider that there is no autocorrelation of residuals.

Since 1.5 > 1.33> 2.5, the autocorrelation of the residuals **is present**.

For more reliable (sustainable) conclusion it is reasonable to address tabular values.
However, the tabulated data seem to be more suitable for a reliable (exact) conclusion,
Using the Durbin-Watson's tabulated data, let find d1 = 1.08; d2 = 1.36 for n=3 and k=1 (a significance level of 5%).
Since 11.08 < 1.33 и 1.36 > 1.33 < 4 - 1.36, the autocorrelation of residuals **is present**.

Verification of normality of residual component distribution

The calculated value of RS criterion is equal to:

$$RS = \frac{\epsilon_{max} \epsilon_{min}}{S_i}$$

where εmax = 5,14 – is the maximum value of residuals, εmin =-5,36 – is a minimum level of the residuals number.
Sε – the mean square deviation

$$Se = \sqrt{\frac{\sum e^2}{n-1}} = \sqrt{\frac{2.478}{3-1}} = 1.113$$

$$RS = \frac{0.754 - (-1.279)}{1.113} = 1.826$$

The calculated value of RS criterion fall outside of the range (2,7-3,7), therefore, the feature of normal distribution is not fulfilled. Thus, the distribution normality of residual component of the model seems to be inadequate.

Conclusions

The performed researches, based on the correlation analysis and evaluations of the parameters for significance, has demonstrated the existence of essential direct correlations between the profit tax paid by the consolidated groups of taxpayers, and the economic growth. This correlation is due to a high concentration of business in the Russian Federation. In 2015, the total number of legal entities registered on January 1 was 4 659 623. 10 largest taxpayers had paid 7,52% of the total profit tax in 2014, 100 largest companies had paid 21,33%, 1000 had paid 36,81%. At the same time 9369 companies (or 0,2% of the total number of the registered legal entities) had paid 50% of the total profit tax proceedings.

Thus, we have to conclude that the revealed correlation of the profit tax paid by the consolidated groups of taxpayers and the importance of the largest taxpayers for budget revenues make any corrections of consolidation order crucially important.

Promising could be researches devoted to an evaluation of amendments concerning the impact of changing the CGT threshold on the federal and regional budgets revenues.

Abstract

Consolidated group of taxpayers (CGT) in Russia, where the profit tax is very important source of regional budgets revenues, intensified importance of profit tax apportionment. The fact that CGT spans multiple regions has caused changes in the established procedures for the distribution of the profit tax among regional budgets. This has induced unpredictable profit tax revenues and conflicts of interests between the affected territories. Starting from 2015, in Russia was proclaimed a moratorium on creating new consolidated groups of taxpayers. This was due to the inefficient formula used for distributing the proceeds from the profit tax paid by the CGT participants. To resolve the situation, we suggest improved approach to the formula used for distributing the profit tax collected from CGTs. The suggested social-economic principle must base on three aspects: the contribution of each region into the state economy and the GDP, implementing factor-based approach, taking into account if the region is depressed (and how much). The suggested approach will facilitate the growth of the social and economic situation in the regions and improve social welfare.

Keywords: tax, consolidated group of taxpayers (CGT), taxation, revenues, regions, profit tax.

Introduction

In Russia, where the profit tax is shared between federal and regional budgets, tax consolidation by groups of companies causes complexity in regional budgets formation. The interregional character of the consolidated group of taxpayers had changed the established order profit tax apportionment among the regional budgets, which caused an unpredictable profit tax revenues and a conflict of interest between the territories.

In 2015 in Russia was proclaimed a moratorium on creation new consolidated groups of taxpayers, up to 2018. This moratorium was declared by reason of distribution the profit tax revenues between the territories. As a result appears distortion of horizontal tax competition. According to the estimations of the Russian Ministry of Finance, in 2014, the profit tax revenue of 53 regions increased by RUR 61.9 billion, those of 32 regions decreased by RUR 127 billion. The share of CGT amounted 3.3% loses from the general reduced profit tax revenue, as a result after creation of CGT the total regional revenues were reduced by 0.6%. In conditions of the economic downturn, the regions lose from the existing profit tax apportionment, and this induces the necessity to compensate this loss for the regions, which had been subjected to the strongest degradation.

Principles of profit tax distribution

According to the performed survey, the methodology of the CGT revenue distribution among the regions should correspond to the following principles:

1) The harmonization of interests– in this case it means an agreement of litigants to accept the model and to execute it without using another sides, indirect mechanisms of impact and pressure. For example, we consider the interest of the main company and its branches, the Federal Centre and subjects of Russian Federation, owners with a multilevel mutual participation of entities in the capital of others;
2) The budget predictability – the redistributive model should be clear and understandable and allow the financial and fiscal authorities to plan relatively expected profit tax revenues, taking into account intractable value of the profit.
3) The justice – in our case, the justice is understand as:
- the socio-ecologic justice meaning that the Russian Federation subjects, which realize mining, initial processing of natural resources must have the priority in taxation of profit. All of these should warrant the compensation of ecological harm and withdrawn non-renewable natural resources. Also to provide the socio-economic priorities for the contemporary population living in this land and its future generations;
- the budgetary and legal horizontal justice – preventing the political and some other pressure of some territorial subjects of Russian Federation upon the mechanism of tax distribution and subsequent financial transfers from the federal center;
- the social and budgetary efficiency - allowing the maximum social effect in the regional multilevel system at minimum expenses of budgetary funds of the regional and local budgets;
4) the joint responsibility - among the group participants arising upon signing the CGT;
5) The unification of approaches to tax obligations - each member of the group must participate in the tax payment as equal;
6) The simplicity of the tax system – defined by the state condition its stability, simplification of calculation procedures and taxation allowing an increase of the tax system efficiency, other conditions being equal;

7) The transparency - the mandatory publication of entity accounts on the performance of the involved CGT groups in the mass media. The report is published by a main company.
In the existing system of consolidated taxation in Russia, the economic welfare is the weakest principle of the CGT orientation, towards the profit tax distribution among the regions. This principle should be based on two aspects.

Firstly, it is necessary to take into account the investment of each region to the development of national economy and the GDP formation. For this purpose, we suggested to use theory of added value to calculate the share of each region the consolidated profit tax. Thus, the basic indicators of the revenue distribution among the regions seem to be: the net asset value, the quantity of personnel (rather than the gross wage) and the operation profit of every CGT participant.

Secondly, it is necessary to apply an indexation, which would include the importance of every indicator for every branch.

Finally, to reinforce the principle of social justice, it is necessary to take into account the degree of region development, in which the consolidated group of taxpayers performs their activity.

Distribution of profit tax paid by CGT among the regions

We suggest the approach based on indicators for reinforcing the social and budgetary principles of the revenue distribution among the consolidated group of taxpayers.

The offered model should be based on the principle of social and economic orientation, therefore, it is necessary to establish:

1. The coefficient to determine the importance of every indicator taking into account the branch structure (the economic importance).

2. The correction indicators taking into account the social efficiency.

Thus, the general formula of the consolidated profit tax distribution among the regions looks like:

$$d = K_{e1} \cdot \frac{K_{si} \cdot T_i}{\sum_{i=1}^{N} K_{Si} \cdot T_i} + K_{e2} \cdot \frac{A_i}{\sum_{i=1}^{N} A_i} + K_{e3} \cdot \frac{\Pi_i}{\sum_{i=1}^{N} \Pi_i}$$

where d – is a profit share for every CGT participant, %;
K_{e1}, K_{e2}, K_{e3} – are the coefficients of economic importance for every indicator;
T_i – is an averaged personnel list or the gross wage of the i^{-th} company participating in the CGT;
K_{si} – is the indicator of social importance (therefore, it is set only for the indicator "quantity";
N – is the number of CGT members;
Ai – is the net wage of depreciation property value of the i^{-th} company – participating in the CGT,
Π – is the profit of the enterprise.
To define the first group of indicators, we have chosen those which reflect the efficiency of application of the factors, proportionally to which the CGT revenue is distributed (Table1).

Table 1: Indicators reflected the efficiency of tax apportion factors applications to CGT

	Factors of profit tax apportionment	**Efficiency Indicators**
1	Net Asset Value	Assets Efficiency
2	Personnel Quantity	Productivity
3	Trading Profit	Production Profitability

To take into account the branch specifics, we analyzed the data of the CGT results. Till the end of 2014, 17 groups of CGT had been established. 47% of them are related to the oil-gas branch (307 companies). The second spot in the ranking is assumed by the metallurgy: 29% or 5 participants (51 companies), the third spot in the ranking is assumed by telecommunications – 12% or 2 participants. One participant of the CGT is related to the banking and energetics, respectively (Fig.2).

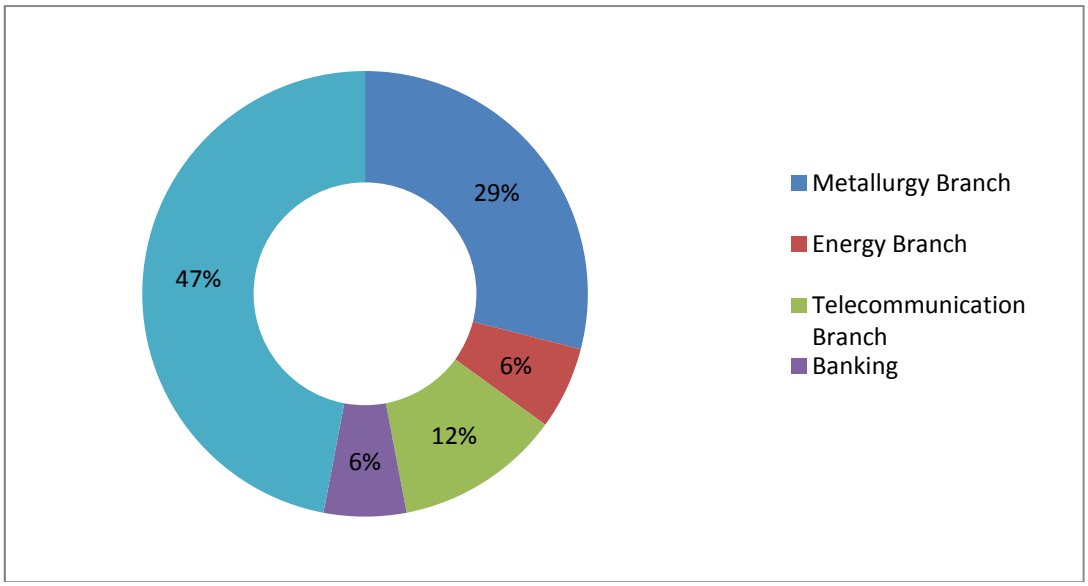

Fig 1. Distribution of CGT according to industrial branches in Russian Federation

In Table 2 we provide data for calculating indicators such as assets efficiency, productivity and production profitability.

Table 2: Database for calculations

Company	Fixed Assets (RUR million)	Personnel Quantity	Profit (RUR million)	Revenues (RUR million)	Asset Efficiency	Productivity, RUR million /person	Saling Profitabillity
JSC "Gazprom"	6722	431	921	3990	0,59	9,25	0,23
JSC "NK "Rosneft"	5666	228	593	5440	0,96	23,86	0,11
JSC "Surgutnefegaz"	1112	102	163	1361	1,22	13,36	0,12
JSC "AK "Transneft"	1706	86	233	774	0,45	9,00	0,30
JSC "Tatneft"	508	21	124	476	0,94	22,92	0,26
JSC "Novatekh"	292	7	128	358	1,23	52,98	0,36
JSC "Gazpromneft"	1294	58	213	1691	1,31	29,40	0,13
JSC "NK "Lukoil"	4583	110	401	8111	1,77	73,73	0,05
JSC "Mechel"	152	80	5	246	1,62	3,08	0,02
JSC "Severstal"	128	52	61	314	2,45	6,04	0,19
JSC "NLMK"	278	30	70	493	1,77	16,43	0,14
JSC "Metalloinvest "	76	60	75	238	3,15	3,97	0,32
" JSC GMK "Norilski Nikel"	394	71	182	456	1,16	6,42	0,40
" JSC Megafon"	225	13	82	315	1,40	24,22	0,26
JSC "Rostelekom"	328	153	40	299	0,91	1,96	0,13
CJSC Bank VTB 24	134	104	112	844	6,32	8,13	0,13
TOTAL	23598	1604	3403	25406	1,08	15,83	0,13

Using the method of multidimensional comparison, the compared figures are reduced to the common value, taking into account the dispersion (Table 3).

Table 3: Averaged efficiency indicators for the oil-gas branch

Company	Asset Efficiency	Productivity	Saling Profitability
Oil and Gas Branch			
JSC "Gazprom"	0,113	0,016	0,418
JSC "NK"Rosneft"	0,294	0,105	0,093
JSC "Surgutneftegaz"	0,478	0,033	0,112
JSC "AK "Transneft"	0,066	0,015	0,711
JSC "Tatneft"	0,281	0,097	0,531
JSC "Novatek"	0,480	0,516	1,000
JSC "Gazprom neft"	0,545	0,159	0,124
JSC "NK"Lukoil"	1,000	1,000	0,019
TOTAL	3,257	1,940	3,008
Coefficient value (indicator proportion)	0,40	0,24	0,37

Thus, the cost of fixed assets plays the main role in evaluations of the performance efficiency for the oil-gas branch. The general formula of the consolidated profit tax revenues distributed among the regional budgets looks like:

$$d = 0{,}24 \cdot \frac{K_{si} \cdot T_i}{\sum_{i=1}^{N} K_{Si} \cdot T_i} + 0{,}40 \cdot \frac{A_i}{\sum_{i=1}^{N} A_i} + 0{,}37 \cdot \frac{\Pi_i}{\sum_{i=1}^{N} \Pi_i}$$

The similar calculations for other branches are summarized in the following Table 4.

Table 4: Averaged efficiency indicators for other branches

Company	Asset Efficiency	Productivity	Saling Profitability
Metallurgy Branch			
JSC "Mechel"	0,27	0,04	0,00
JSC "Severstal"	0,61	0,14	0,24
JSC "NLMK"	0,32	1,00	0,13
JSC "Metalloinvest"	1,00	0,06	0,62
JSC "GMK "Norilski Nikel"	0,13	0,15	1,00
TOTAL	2,32	1,38	1,99
Coefficient value (indicator proportion)	0,41	0,24	0,35
Telecommunication Branch			
Coefficient value (indicator proportion)	0,37	0,31	0,32
Banking and other Branch			
Coefficient value (indicator proportion)	0,31	0,38	0,31

Thus, we can conclude that, the most important indicator for the oil-gas and metallurgy is an efficient use of the fixed asset. It can be explained by the specifics of branches which need high volume of fixed assets. In other spheres, all three indicators are practically equal. The chosen values of indicators seems to stimulate the realization of socio-ecologic equity principle, since the dominating revenue will be distributed into the Russian Federation subjects, where the gross wage of companies is allocated. It would compensate the ecological damage and withdraw of non-renewable natural resources.

We should take into account the degree of region development, in which the consolidated groups of taxpayers perform their activity to realize the social component of the offered technique.

The evaluation of the depression rate is very important for analysis of the socio-economic justice. There exists the technique of additional revenue distribution for poorly developed regions, which had been implemented by the Russian Federation Government in September 19, 1998, N 1112. The calculation is based on the budget endowment of the expenditures for socially important points by the income taking into account the financial assets not having the financial sources over a financial year, nor the mortgagee debts. The main criterion to define the depressive region, in this case, is the calculated overhang of expenditures over the budget revenues.

In 2013, was prepared the project of Federal Law N91010-3 (About the Principles of Federal Support of Harmful Russian Federation Territories), which defined more exactly the criteria of evaluation and formalization for such regions. A number of experts consider the multiple deceleration of production activity of key branches, which occurred for the recent 15 years, the unemployment exceeding the total over-Russia rate, and the reduced income compared to the living wage, as the criteria of depressive region.

We suggest to complete the technique defining the depression rate for regions, in which the CGT participants perform their activity, for the purposes of taxation. We also offer to define the depression rate of four levels – an extremely depressive region, an above-average one, a lower-average region, and a non-depressive region. This technique is to be enacted. The depression rate should affects the value of *Ks* coefficient (Table 5).

Table 5: The value of Ks coefficient

Rate of region's depressiion	K_{si} value- coefficient of social-significance
Extremely depressive region	4
Above-average depressive region	3
Under-average depressive region	2
Non-depressive region	1

Conclusion

Thus, ranking the region over the scale of depression state we could increase the revenues of CGT participants into the budget and raising in this way the socio-economic state and the population welfare. In our opinion, the offered method of the consolidated profit tax distribution seems to allow the company management and regional authorities to consolidate efforts increasing, in this way, the functional efficiency of companies expressed in creation of new working places, investment, as well as returns from the invested capital. These efforts would promote an increase of the socio-economic status of regions and enhancement of the society welfare.

Abstract

Sustainable competitive advantage is important when companies keep searching new ways to offer value better than their competitors, especially when the competitive environment changes. Knowing which elements of competitive advantage to deploy would help companies set effective competitive strategies from the very beginning. Intellectual capital as intangible resources is important for a sustainable competitive advantage. The main concerns of this paper are to identify the elements of sustainable competitive advantage of small and medium enterprises and how intellectual capital influences sustainable competitive advantage. Focus group approach was used to explore the perception of sustainable competitive advantage and intellectual capital of SMEs. Content analysis was analysed using a mechanical method. The findings show that cost leadership and differentiation strategies are commonly used by SMEs to achieve sustainable competitive advantage. In addition, innovation is considered vital to create value for customers. The majority of the participants agreed that human capital is the most important element of intellectual capital regardless of industry. Innovation capital is regarded more important than relational capital and structural capital.

Keywords: Sustainable Competitive Advantage, Intellectual Capital, Small and Medium Enterprises

Introduction

In a turbulent and competitive environment, having competitive advantage will help a company stay profitable and ahead of its competitors. However, competitive advantage alone does not guarantee the company will remain relevant. Companies should strive for sustainable competitive advantage to remain in the business for the long term. This can be achieved by leveraging and capitalising their internal resources and capabilities. Intellectual capital is a key driver of innovation and competitive advantage in a knowledge based economy (Taie, 2014; Guthrie and Petty, 2000) where learning and knowledge are the key parameters of sustainable competitive advantage (Hana, 2013). Most studies on competitive advantage and intellectual capital employ the quantitative approach gather general ideas or perception of large population which means that the real and hidden answers were not recorded. Furthermore, SMEs have limitations compared to large organisations such as limited resources, lack of experts, and lack of impact especially in strategic approaches, role of owner/manager and lack of formalised policies and practices (Darcy et al., 2014). A qualitative study would help explore in depth of sustainable competitive advantage, intellectual capital, and innovative intelligence among entrepreneurs. This paper investigates the sustainable competitive advantage of SMEs and the link of intellectual capital and innovative intelligence of SMEs in Malaysia through the use of focus group.

Sustainable Competitive Advantage

Competition has forced SMEs to set their competitive advantage (Kocoglu et al., 2009; Hana, 2013). They have to identify new ways to satisfy their customers and provide value better than their competitors. When customer value firms offer more than that of their competitors, they attain competitive advantage (Choplin, 2002; Ipek, 2009; Ismail, 2014). Kotler (2000) defined competitive advantage (CA) as the capability of the organisation to carry out its activities in ways other cannot imitate. By having its CA, the firm builds its base for a strategy (Daou et al., 2013). A firm that differs from its competitors and remains outstanding to their consumers would gain sustainable CA (Darcy et al., 2014; Gonzalez-Loureiro and Dorrego, 2012; Khan, 2014). CA lies in the resources and capabilities that produce products or services (Papula and Volna, 2013).

Sources of CA depend on the internal resources or assets of the organisation either tangible or intangible. Tangible assets comprise financial, physical, and technological assets while intangible assets are human, innovation, creativity, and reputation (Papula and Volna, 2013). They emphasised that the source of CA is an intangible asset comprising human capital, structural capital, relational capital, and customer capital. In contrast, according to Alawneh et al. (2009), SMEs have unique characteristics that prevent them from developing a CA compared to large organisation. Nevertheless, Papula and Volna (2013) highlighted that SMEs can more easily differentiate from their competitors because they are fast to adapt to the changing environment compared to larger organisations.

Based on resource based theory, CA can be achieved if the organization's resources are valuable, rare, hard to imitate, and non-substitutable (Barney, 1991). Porter (1980) established three generic strategies which are cost leadership, differentiation, and focus. Cost leadership strategy focuses on cost reduction by selling cheaper than competitors. Differentiation strategy is where companies differentiate their products by features, product mix, services and product complexity. Focus strategy concentrates on a market niche where the company tries to maintain its market leadership. A company can achieve its CA either by operating at a low cost, or by charging a premium price, or by doing both (Porter and Stern, 2001). A survey in Europe found that differentiation strategy is more attractive and suitable to small companies as they are more innovative (3i European Enterprise Centre, 1994).

Barney (1991) emphasised that a firm possesses sustained CA when it adopts a strategy that is, "not simultaneously being implemented by any current or potential competitors and when these other firms are unable to duplicate the benefits of this strategy." According to Coyne (1986), sustainable competitive advantage is when the company is able to maintain the durability of its attractive attribute gap for a certain period of time. As long as competitors cannot fill the gap, the company has a sustainable competitive advantage.

Intellectual Capital

Intellectual capital (IC) has gained popularity, especially in the knowledge based economy. IC studies have focused on large organisations. Studies of IC have extended to SMEs to help them perform better. Generally, IC is knowledge, information, skill, experience, intellectual property that can be put to use to create wealth (Stewart, 1997). Bontis (1998) further elaborated that IC is about the pursuit of the effective use of knowledge (the finished product) as opposed to information (the raw material). Cohen and Kaimenakis (2007) concluded that IC comprises valuable intangible resources containing knowledge that can be used by the firm to accomplish its goals. However, these intangible resources must be complimented with effective management to provide the firm with sustainable competitive advantage. Basically, IC can be located in its people (human capital), its structures (structural capital) and its relationship with stakeholders (relational capital) (Bontis, 1998; Marr, 2008; Ling, 2012;

Human capital (HC) comprises employees' skills, commitment, competence, attitude, capabilities, talents, creativity, and knowledge as an organisation's intangible assets that can be turned into CA (Cohen and Kaimenakis, 2007; Chen et al., 2004). HC can be described as, "knowledge, skills and experience employees take with them when they leave the company' (Djurica et al., 2014).

According to Mouritsen et al. (2002), HC contains creativity, innovativeness, initiative, adaptability, flexibility, motivation, persistence, expertise, skills, experience, devotion to organisation, teamwork training, flexibility, loyalty, ability to establish and develop relations with other employees in the company and its partners, readiness to accept changes, and ability to learn.

IC by itself is of little value without the leveraging effect of the firm's supporting structural capital resource. The structural capital (SC) comprises systems, structure, corporate culture, the organisational process efficiency, databases, information and production technology (Cohen and Kaimenakis, 2007). SC is the embodiment, empowerment, and supportive infrastructure of HC (Bontis, 1998). SC provides a platform for people to be creative (Stewart, 2000). It is owned by the firm. The management's dedication and efficiency is important for the firm's sustainable competitive advantage (van Zyl, 2005). SC comprises innovation capital, organisational capital, and process capital.

Relational capital (RC) embraces all the relations the firm has established with its stakeholder groups such as customers, suppliers, the community, and the government (Bontis, 1998; Allee, 2000). Specifically, RC fosters a knowledge-producing behaviour – providing a source of ideas for change and improvement by market information processing and marketing strategies (Keskin, 2006). However, this knowledge has little benefit if not appreciated and implemented to enhance firm innovation. According to Martin-de-Castro et al. (2004), IC, especially RC is very much into social networking where the relationship with external parties such as customers, suppliers, and the government play a crucial role in the organisation. However, Mc Elroy (2003) commented that IC itself does not emphasise the value of the relationships between people in firms and between firms and other firms.

More capital has been introduced to help companies achieve better performance and acquire sustainable competitive advantage. Innovation capital (Chang and Hsieh, 2011) and technological capital (Pedro et al., 2010) have helped companies capitalise their knowledge and turn it into innovation and intellectual property.

Sustainable Competitive Advantage and Intellectual Capital

IC components especially HC play a crucial role in establishing and maintenance of CA of a company (Djurica et al., 2014). Knowledge that resides in HC, SC, and RC is a source of a company's competencies and are thus vital in building sustainable CA (Lopez et al., 2006). The interactions of IC elements can result in sustained competitive advantage (Gannon et al., 2009). Researches have highlighted that IC is the basis for the generation of sustainable competitive advantages, and this relationship has been broadly studied in the case of medium and large-sized organisations (Ugalde-Blinda et al., 2014; Gannon et al., 2009; Daou et al., 2013; Akhtar et al., 2015).

Methodology

This is a qualitative and exploratory study. Focus group can be defined as, "a small group of people selected to discuss on a particular topic which is led by a facilitator" (Reinard, 1999 as cited by Kratt, 2003). According to Stokes (2000), focus groups provide the possibility of a shift in the power balance from the researcher to entrepreneurs. Furthermore, focus groups allow participants to focus on the researcher's emphasis (Threlfall, 1999). The focus session provides useful information on participants' perception, experience, and knowledge in their own terms and language (Stewart and Shamdasani, 1990). This paper intends to capture this primary information.

The participants for this study were selected through nonrandom methods. Purposive sampling and networking were used to identify the target group and invite volunteers to participate (Latham, 2007). Personal contact was used to identify the target group and the participants. Participants were informed of the date and venue of the session. Eleven entrepreneurs agreed to attend the session which is within the conventional group size of six to 12 (Millward, 2012; Cameron, 2005).

Two prime considerations for participants are convenience and comfort. We reserved a small business room that can accommodate 15 people. The participants were seated at a big round table so that they would be able to hear and listen to others clearly. Since all the participants are entrepreneurs, they were willing to participate in a two hour session. The success of the session will depend on preparation and good people skills (Greenbaum, 2000; Wilkinson, 2003 as cited by Millward, 2012). Three facilitators and two research assistants were deployed for this purpose.

Prior to the focus group session, a list of questions was prepared. The questions included: what is the sustainable competitive advantage to your firm, what elements of CA are for the firm, which of the elements are important for sustainable competitive advantage for your company and which of the IC elements is the most important for SMEs? During the session, an audio recorder was used to tape the discussion. The entire discussion was recorded directly on tape.

There is no single way to analyse the focus group data (Wilkinson, 2003). The form of analysis will depend fundamentally on whether it is the "content" or the "interaction process" that is the "data" of interest (Millward, 2012). The discussion of content analysis is used to analyse transcription data which can be done either through mechanical or an interpretative component (Krippendorf, 1980 as cited by Millward, 2012). For this study, a mechanical aspect involving physically organising and subdividing the data into categories is adopted.

Research Design

The participants for this study were selected using nonprobability sampling method. Nonprobability sampling is subjective whereby not all members of a population have an equal chance of being selected (Cooper and Schindler, 2003; Reinard, 1999 as cited by Kratt, 2003). The participants were selected on the basis of their accessibility or by the purposive personal judgement of the researcher. For this study, nonrandom tactics used included purposive sampling and networking. The researcher contacted an entrepreneur who is a member of few entrepreneurial associations. The researcher then requested her to extend the invitation to other entrepreneurs who met the requirements of this session. Eleven entrepreneurs agreed to participate in the focus group session.

Results of the Study

The results from the focus group discussion protocol are presented. It is organised under the sustainable competitive advantage, IC, and general reflections.

Sustainable Competitive Advantage

Sustainable competitive advantage (SCA) is important for SMEs to remain relevant in the industry. Depending on the industry, the focus on the elements of SCA would differ as stated by one participant that, *"between cost leadership and product differentiation, it depends on what stage the company is which is life-cycle…"*. Furthermore, the stages and level of maturity of SMEs are other factors that influence the focus of SCA. For example, in the service industry, cost leadership is more important than product differentiation as stated by one of the participants, *"For the service industry, I think cost leadership is more important because it is reflected in our financial budget…"* Another view of one of the entrepreneurs, "*I think depending on the industry, for example for manufacturer they have to focus on product to create CA, however, in service industry basically very competitive. You can imitate your competitor, your competitor could be your benchmark but at the end of the day, you must set your own CA."*

Most participants agreed that cost leadership and product differentiation strategies are equally important and have to be included in the company's CA strategy. However, depending on cost leadership and product differentiation strategies is not sufficient to sustain and maintain their position in the industry. In this study, innovation has been proposed as an element of SCA. In order to sustain the CA, *"…innovation is what we must do to sustain"*. *"I think when we are talking about SCA, we have to focus on innovation which means you to be innovative every day, every month together with*

your employees and so the company's CA can be sustained in the market". The company has to be innovative in creating value for customers and being different than its competitors, *"SCA for us is create value and do differently"*. As innovation is important in SCA, innovation performance should be included as an organisational performance measure. *"Cost-leadership is important to my company. Product differentiation is also what we must have, we should do what our competitors are not doing and do better than them where product and process innovation are important today"*. However, one of the entrepreneurs disagreed, as for her company product differentiation strategy and innovation performance are more important than cost leadership strategy.

Intellectual Capital

In a knowledge based economy, knowledge, which is an intangible resource, is more important than tangible resources like labour and capital. IC comprises HC, SC, and RC has evolved to help the organisation to perform and better acquire SCA. As IC goes in-depth, capitals like technological capital, innovation capital, and spiritual capital have been included. The participants agreed that all IC elements are important for achieving SCA. They are not familiar with the terms and did not realise the importance to identifying and capitalising on IC as stated by one of the entrepreneurs, "*I am glad that today I learned what IC is about. We don't have a proper plan but we have a goal. What we do we just set out our goals and do whatever necessary to achieve it"*. After the explanation of IC, the entrepreneurs were given questions on IC. Some thought that spiritual capital should be included, *"…spiritual capital is important in my company. Spiritual capital is about honesty among staff. Therefore, in order for them to be honest, it is good to have spiritual capital"*. However, another participant disagreed with including spiritual capital, *"I think spiritual capital can become very religious meaning I don't need money… I don't need anything"*.

Participants had mixed views on the importance of IC. One participant stated, *"For my training company, HC is a main priority, follows by RC, innovation capital, SC and technological capital"*. For another training company, *"For me HC is very important, then SC, RC, innovation capital and technological capital"*. SC is whatever is left behind after office hour which includes a database, system etc. *"…some of the structural elements are costly; there are many ways to cut costs. We know many ways to cut costs, for example, we fully utilised google.doc. Whatever transpired between customers and employees, all information will be shared among the employees through cloud application such as google.doc.…". We share information on google.doc between our staff and customers.*

Overall, all the participants agreed that HC is the most important element of IC as stated by a participant, *"even if you have the best SC but not HC, everything will be collapsed"*. For entrepreneurs from the IT industry, *"…in my industry, innovation can be easily duplicated. I have to innovate quickly ahead of my competitors. I have to understand my customers' needs and provide innovative solutions. Therefore, I would say HC is our main priority while innovation capital is next important element. The rest are equally important"*. For another entrepreneur, *"in SMEs we have to invest either in human or relationship. For me, RC is more important than HC"*.

Conclusions

Most entrepreneurs are unaware of how they achieve their CA. They have their own strategies which were rather general and on an ad-hoc basis. It is interesting to discover that entrepreneurs prefer to adapt strategies for cost leadership and product differentiation. The entrepreneurs agreed that in order for SMEs to acquire SCA, they must adopt cost leadership, product differentiation, and innovation performance. However, depending on industry and its life-cycle, SMEs did not necessarily adopt all three dimensions of the proposed SCA but select the one that gives them most advantage.

SMEs understand the importance of IC to achieve SCA. HC is considered the most important elements of IC. Although all capitals are considered important, innovation capital ranks second after HC. Interestingly, entrepreneurs did not rank SC as high as RC which is in contrast to Bontis et al. (2002) and Chen (2004). A qualitative research design proved fruitful in obtaining a description of

practices from entrepreneurs (Stokes, 2000). The focus group session helped the researcher acquire in-depth information which would not be obtained through a quantitative approach. Even though primary information was attained from the entrepreneurs, the findings are not generalisable (Threlfall, 1999). Innovation is important to businesses as highlighted by the entrepreneurs, especially in a creative and knowledge based economy.

This study showed that most of the entrepreneurs set their strategies based on their intuition without knowing the importance of CA. Their main target is to create value so that they are ahead of their competitors. It is important for entrepreneurs to develop their strategies to capitalise on their IC effectively. In addition, the term "IC" seems new to entrepreneurs. It would be beneficial if entrepreneurs knew the benefits of IC and how it would affect and influence their CA. This study was carried out on a small number of entrepreneurs from different industries and with different background. It would be interesting to select participants from a single industry to gathering information on their SCA and IC.

Competitive Devaluation in the Context of Commercial Neo-Protectionism

PhD Alexandru Butiseacă, Romanian American University, Bucharest, Romania,

Abstract

In the current economic context, competitive devaluation has become a common practice both in emerging and developed economies. But, despite their more or less recent popularity, economic advantages of competitive devaluations are only apparent, involving huge long-term costs, inclusively for practicing states.

The main purpose of the present research is to reveal the economic and political consequences of currency devaluations and, also, to critically assess the neo-protectionist thesis that a country need to maintain a balanced trade with all their commercial partners. The paper contains also a brief analysis of competitive devaluation policies applied in China. The main finding of our research is that, although China is in the top of international statistics on export, the Chinese people hasn't got anything to gain in the long run, in terms of prosperity and economic wealth. In fact, exports' stimulation through currency devaluation is a hidden form of export subsidizing, i.e. subsidizing importing countries consumption of Chinese goods. Therefore, in the end, the country enforcing currency devaluation and, consequently, diminishing the purchasing power of the domestic currency, succeeds only to subsidize the consumption of foreign customers from the importing countries on account of lowering the income of its own citizens.

The proposed paper is mainly a theoretical research, aiming to refine existing arguments, to bring new arguments, and also to discuss relevant examples and cases for the announced topic.

Keywords: neo-protectionist, economic and political consequences of currency devaluation, China's neo-protectionism, competitive devaluation policy in China

Introduction

In the current economic context, the competitive devaluation of currencies has become common practice, the main goal being to encourage exports and reduce imports. This kind of policy is the hallmark of the neo-protectionism, current of thought that dominates currently international trade theory. According to neo-protectionist thesis a country need to maintain a balanced trade with all their commercial partners. This thesis stands in opposition with the free-trade basic idea, namely that trade deficits between countries occur naturally on the free market and they do not represent an undesirable situation *per se*.

The main purpose of the present research is to reveal the economic and political consequences of currency devaluations using both theoretical arguments and relevant cases and examples. In the first part of the paper, two of the main conceptions and theses, lying at the basis of the protectionism and neo-protectionism's rhetoric are criticized: (a) the holistic conception presupposed by the balance of payment calculation (i.e. the aggregation of individual transactions) and (b) the thesis according to which a country must have a balanced trade or must record trade surplus. The second part of the paper contains a theoretical analysis of economic and political consequences of competitive devaluation policies, while in the third part theoretical conclusions are illustrated, analyzing the case of neo-protectionism and the competitive devaluation policies applied in China.

Currency devaluation and Competitive Devaluation

Currency devaluation entails the application of certain monetary policies by the central bank of a country which lead, *ceteris paribus*, to a reduction in the value of domestic currency in relation to other foreign currencies. The objectives of such currency devaluation can be various: (a) to keep nominal wage rates at constant level or to increase them while decreasing actual wages; (b) to favor debtors to the detriment of creditors; (c) to encourage exports and reduce imports etc. (Mises 2008, 783-784). The competitive devaluation of a country's currency is meant to reduce the prices of the goods made by local companies in order to make them more attractive for foreigners. Moreover, in this manner, foreign merchandise becomes more expensive, and thus the objective of imports' reduction is thus achieved.

The first competitive devaluations occurred in the '30s, following the Great Depression and in the context of the abolition of the gold standard by Great Britain in 1931. Since 2000, in particular after the 2008 financial and economic crisis, competitive devaluations have become more frequent, under the form of the so-called "currency wars" (Lutsyshyn and Reznykova 2013, 58). The People's Republic of China is well-known for its policies of currency devaluation. Since the '80s, China has launched its mercantilist strategy to achieve commercial surplus, subsequently supported financially through successive currency devaluations. Lutsyshyn and Reznykova (2013, 52) have pointed out that, following such successive devaluations, the labor costs in China came to be even 80 times lower than in the USA, while in other developing countries such costs are 40 times lower than in the USA.

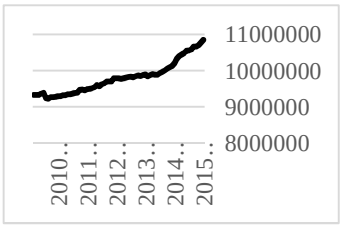

Fig 2. Evolution of monetary aggregates in the Euro area, 2010-2015 (millions of euro)

Source: Authors' representation based on European Central Bank data, 2015

In the 2000s, most countries in transition or emerging economies resorted to the competitive devaluation of currencies. After the 2008 economic crisis, developed countries also entered this game of competitive devaluations. For instance, in January 2015, the European Central Bank announced the implementation of a program to buy government bonds and private sector assets worth 60 billion euro per month until September 2016. Since February 2015 to November 2015, the monetary aggregates (M3) in the Euro area increased from 10438 billion euro to 10850 billion euro (Fig 1). In 2010, the monetary aggregates (M3) in the Euro area was around 9290 billion euro (Fig 2). The decision of the European Central Bank follows the same logic of competitive devaluations, given that such measure has been aimed at stimulating European economies, many of them in economic stagnation or recession.

Neo-Protectionism Rhetoric: A Critical Approach

The neo-protectionist thesis, reminiscent of mercantilist thinking, states that a country need to maintain a balanced trade with all their commercial partners, and even to target commercial surplus. Otherwise, protectionist "adjustments" might be required. If a country had a trade deficit the main policy prescriptions of mercantilists was the reduction of the consumption of imported goods. The implicit assumption was that the rights of individuals to consume, to buy, to sell, to invest etc. need to be limited according to the balanced trade schema.

This section focuses on criticizing two of the main conceptions and theses, lying at the basis of the protectionism and neo-protectionism's rhetoric: (1) the holistic conception presupposed by the balance of payment calculation (i.e. the aggregation of individual transactions) and (2) the thesis according to which a country must have a balanced trade or must record trade surplus.

(1) The first issue is the aggregation of individual transactions and the methods of recording them in the balance of payment. Starting from the principle of methodological individualism, we assume that the data collected in the balance of payment statistics is more significant if it has a meaning for economic agents of an economy. In fact, those who start and complete any activities related to imports or exports are the individuals and not such abstract entities like national economies. Assessing the relevance of the balance of payment statistics for each individual engaged in market exchange, brings lights to the deficiencies of the holistic approach of international trade and especially of the balance of payment.

The main issue is the aggregation of inhomogeneous data, which actually make sense only from the perspective of the individual who acts. For instance, in a trade balance of a country are aggregately recorded entries and exits of goods and services without considering that some individuals "get their income from selling tangible goods on the domestic market and spend their income, entirely or partially, as consumers of imported goods, or that some agents buy production factors from abroad and sell them in the country, abroad or make a combination of the two" (Spiridon, 63). Moreover, an aggregate recording of international transactions of goods and services does not consider that the period relevant to individuals not necessarily match the period taken into account in the calculation of national trade balance (the calendar year). Moreover, at the aggregate level, it does not matter if the parties involved in the exchange make profit or not, but only the contribution to the increase or decrease of the trade deficit is considered. However, without taking into account whether analyzed international transactions are mutually beneficial for the parties involved, the statement according to which a country's trade balance is unfavorable because its imports exceeds exports is either irrelevant or misleading.

(2) The second issue is the idea that a country's exports should exceed imports, on the basis that a country's trade balance is "unfavorable" when a deficit of the current account is recorded. Firstly, there are a number of problems and ambiguities related to the methodology typically employed to calculate the current account deficits or surpluses[1]. For example, in the calculation of the current account the sale of financial assets are not included, these being added separately in the capital account. If a current account deficit is recorded, the trade balance is considered "unfavorable", according to the protectionist rhetoric. Actually, the current account deficit is counterbalanced by a surplus in the capital account (Irwin, 2009, 138). Thus, it is unwarrantedly assumed that a current account deficit is undesirable, without taking into account the surplus in the capital account. After all, a country's current account deficit reflects an increased demand for foreign goods and services, compared to a decreased demand for domestic goods and services; while the surplus in the capital account is triggered by a higher demand of foreign investors for domestic financial assets, compared to a lower demand of domestic investors for foreign financial assets. There is no necessary connection between a balanced trade and economic prosperity of a nation. On the contrary, there are multiple counterexamples showing that during periods with high trade surplus for some countries, their economic situation was terrible (e.g. the USA during the Great Depression). Another example is the case of autarchic or isolated economies, obviously without any trade deficit, but whose citizens cannot be considered as enjoying economic prosperity. This is the reason why economists often warn that an "intense focus on sets of data – the aggregates themselves – might make us lose sight of specific, often heterogeneous information that individuals make use of to coordinate their daily plans and projects." (Heyne *et al.* 2011, 368).

Secondly, let's return to premises and analyze, from the perspective of methodological individualism, the thesis according to which current account deficit is undesirable. As one individual cannot produce everything by himself, a country cannot specialize in all types of economic activities and, therefore trade exchanges are necessary both at individual and country level. Purchasing cheaper economic goods from abroad cannot be a disadvantage; notwithstanding this is exactly the neo-protectionist

interpretation of international trade statistics. The condition of a person forced not to make exchanges with the "outside world" or to do so only under certain restrictions, could not be considered "favorable". A bilateral deficit, such as the deficit of country A in relation to country B, only means that the citizens from country A (given an increased purchasing power of their domestic currency, for instance) bought in one year more goods from the citizens from country B. Those in country A own the desired goods and those in country B own the currency; the payments were made or will be made. There is nothing to be balanced, the attempts to achieve a balanced trade through protectionist measures reflect a poor understanding of the international trade problem. Import restrictions are usually enforced by trade tariffs, which have the well-known unfavorable consequences, without even leading to a balanced trade. Trade tariffs affect the profitability of certain imports, which leads to a decrease of imported goods and services, but there are no beneficial effects regarding exports – "only in books" exports remain not affected. Importers owning the foreign currency want to spend it. "Even if the foreign currency is spent on other imports or on domestic goods, the result will be the same: imports at similar levels or decreased exports" (Spiridon, 118). In other words, *ceteris paribus*, a decrease in imports implicitly leads to a decrease of future exports. Also, an increase in exports implicitly leads to an increase of future imports (Hazlitt 2008, 69). In fact, imports enable exports and their limitation cuts the possibility of future exports instantly. The foreign currency received by the exporting country will be used by exporters or by interested parties from the exporter's country (or by individuals from other countries where the exporter spent the currency) to purchase goods and services from the importing country; otherwise the exporting country will not thrive economically. Therefore, the idea according to which individual or country prosperity depends on a balanced trade or on trade surplus is not economically justified.

Thirdly, there other important things when considering the adequacy of reducing the trade deficit, respectively: (a) the fact that exchanges do not occur between two nations, but are multilateral and also (b) the case when trading countries are of different size in terms of population: even if both counties exchange the same amounts of products per capita there will be a trade deficit for the less populated country. Thus, both countries benefit from voluntary trade even so there is a trade deficit (Mcgee 1996).

Therefore, we can conclude that trade deficits between countries occur naturally on the free market and they do not represent an undesirable situation *per se*. However, there are cases, especially since competitive devaluations became a current practice, when trade deficits occurs precisely because of different types of governments interventions, such as competitive devaluations and exchange rate manipulation. In such cases, protectionist measures only make things worse, the only acceptable solution being to abandon policies of competitive devaluation, which caused persistent trade deficits between countries.

Economic and Political Consequences of Currency Devaluation

The Illusory Economic Advantages of Currency Devaluation

What happens if states interfere economically to stimulate exports by currency devaluation? Are they economically favored in any way?

Ludwig von Mises (2008, 785) emphasize that the much talked about advantages which currency devaluation secures in tourism and external trade fully arise from the fact that the adjustment of prices and wages to the new state of affairs created by devaluation requires time. During this period of adjustment, exports are encouraged and imports discouraged, but the citizens from the country enforcing currency devaluation receive less for the goods sold abroad and pay more for goods exported by countries that do not devalue their currency. Therefore, although this effect seems like a benefit to those for whom the trade balance is the ultimate standard of domestic welfare, the citizens in the countries enforcing devaluation actually lose. For instance, if UK enforce currency devaluation, the British citizens has to export more British goods to buy the same quantity of tea they received prior to devaluation in exchange of a smaller quantity of exported goods (Mises 2008, 785).

In the context of currency devaluation, domestic goods become cheaper for foreign consumers. They can buy with the same currency unit more of the currency of the country that enforced devaluation. More exactly, the population has no gain from the devaluation of domestic currency and the taxpayers finance the consumption of citizens from importing countries that are the only ones to gain from such policy. Apparently, exporters from countries practicing currency devaluation are also privileged. Part of exporters may have, indeed, higher temporary profits from the increased demand for the goods and services they offer, but these holds only as long as adjustments of prices and wages are not yet completed on the domestic market. Once these adjustments are completed, the exporters' profits decrease or disappear. On the long-term, exporters might be at a loss or even go bankrupt if they do not anticipate the adjustments occurring on the market in terms of relative prices and wages following currency devaluation. Not lastly, we also have to consider that the exporters from a country enforcing competitive currency devaluation policies, can be adversely affected from a different perspective: for example, if exporters use imported elements to produce the final product they export. Moreover, the decrease in the purchasing power of the domestic currency will eventually affect the income of all agents on the domestic market, including exporters' and if currency devaluations occur through credit expansion, the economic cycle might appear with all its unpleasant consequences. However, competitive devaluation (to stimulate exports and decrease imports), irrespective of its occurrence, is a form of subsidizing exports, incurred by the citizens of the country where it is enforced.

The Increase of Calculational Chaos and the Ratchet Effect

Devaluations can be enforced by different methods. It is not our purpose to present a full taxonomy of the methods and techniques used by central banks to carry out currency devaluations, but we will focus on several examples, detailing their economic and political effects. Thus, two of the central banks' most well-known methods to devaluate currency are: (a) to increase the supply of domestic currency (monetary injection) purchasing foreign currency at the same time; (b) operations on the free market: the central bank buys government bonds and other types of assets, which could lead to the phenomenon of credit expansion.

Both methods of currency devaluation have adverse economic, social and political effects, but the inflation arising from credit expansion can include, among other different consequences, the increase of calculational chaos and economic cycle.

The terrible effects of the inflation generated by the artificial increase of the monetary aggregate are detailed, for example, by Ludwig von Mises (1998, 35-39) and G. Hülsmann (2008, 175-178): (1) debtor advantages and creditor disadvantages; (2) the purchasing power of the monetary unit decreases below the one which would have prevailed on a free market; (3) significant profits for the first beneficiaries of the new currency established on the market to the detriment of other agents (*i.e.* the Cantillon effect). For example, if the money newly entered on the market goes to arms manufacturers, the entrepreneurs and workers from these industries will be the first to make gain following inflation. All the other entrepreneurs and their employees will face increases in the prices of goods and services on the market and will incur losses until the prices of their own products will increase (Mises 1998, 36). The policy to stimulate exports and discourage imports through the devaluation of the domestic currency relies on this type of effect. Mises (1998, 36) emphasized that exporters benefit on the short-term, while the prices and wages adjust on the market. When the prices of all other goods and services rise as well, the exporters' disadvantages disappear.

If, for instance, currency devaluation is made through the mechanism of credit expansion, the list of probable consequences could include the boom bust economic cycle and also the increase of calculational chaos. Ludwig von Mises (1998, 39) has analyzed the causes of malinvestments during economic booms and showed that they are closely related to the decrease of bank loans' interest rate in the context of credit expansion. The decrease of the bank loans' interest rate does not change, however, how individuals evaluate on the market present goods compared to future goods. When the interest rate reflects again the time preference of individuals, readjustments will be necessary and

they could lead to losses and even bankruptcy for the entrepreneurs who took wrong investment decisions. Credit expansion does not generate more wealth and more goods, but induce errors in the calculations of entrepreneurs who evaluate erroneously the profitability of certain investments. In the context of a lower interest rate on loans, entrepreneurs bid for production factors and labor, overestimating the profitability of their investments. When, sooner or later, the interest rate returns to the point where it reflects the actual difference (on the market) between present goods and future goods, the adjustment process occurs and its effects are described by the theory of the economic cycle. If credit expansion bring profitable loans for exporters, the speculative bubble might occur in the production for export, entailing malinvestments and, thus, losses and bankruptcies for exporters and all related fields.

In fact, credit expansion phenomenon generates perverse incentives that encourage recklessness in entrepreneurial and managerial decisions. Entrepreneurs are allowed to access artificially cheaper loans to finance their companies. This will lead often to glaring malinvestments[2]. In such a business environment, the number of authentic entrepreneurs narrows down. Moreover, consumption is stimulated to the detriment of saving, because individuals will rather avoid to keep their savings in an inflationary currency. Abnormal indebtedness of companies and private individuals is also encouraged. Furthermore, in an inflationary economy, essential principles such as responsible behavior and moral conducts of persons are weakened (Hülsmann 2008, 175-188).

Inflation may stimulate increased intervention of central governments in various domains and Ratchet effect might occur (Higgs 1989, 57-77): once government's intervention expanded, usually in the context of a crisis (real or apparent), subsequently it does not shrink back to the level that existed before. Thus, through increased inflation large government projects in various domains might be financed, but of doubtful efficiency and without explicit public agreement, because citizens usually does not realizes the connection between the decrease of the purchasing power of money and the increase of government spending. Besides, inflation enables governments to finance wars or to dawdle existing wars. But, as R. Higgs (1989, 57-77) explains, once such government projects or activities started, the process might prove quasi-irreversible. Most of the time, new government projects entail the creation of new bureaucratic structures and new categories of government expenses, which get perpetuated over time. The expansion of the state intervention usually occur in the context of actual or apparent economic crises. Likewise, currency devaluation occurs in the contexts of recessions or economic crises and usually it is also a quasi-irreversible policy in current political environment. It is contended that such measures stimulate economic growth, and that there is a direct relation between balanced trade rhetoric and economic growth. But as we emphasized in this article, currency devaluation entails only disadvantages on the long term.

Neo-Protectionism and the Competitive Devaluation Policy in China

The yuan devaluation is part of the neo-protectionist model promoted by Chinese officials in the early '90s meant to increase exports and to bring about rapid growth and high rates of employment (Schmid, 2014). Our thesis is that, although through such policies China is on the top of international statistics on export, the Chinese people hasn't got anything to gain in the long run, in terms of prosperity and economic wealth. In fact, exports' stimulation through currency devaluation is a hidden form of export subsidizing, i.e. subsidizing importing countries consumption of Chinese goods.

The People's Bank of China – PBOC controlled the yuan/US dollar exchange rate buying US dollars from the Chinese exporters at a fixed rate and issuing yuan in exchange (Rajan 2010, 219). Empirical data denote a constant increase in China's foreign exchange reserves between 2000 and 2014, from 156100 million US dollars in January 2000 to almost 4000 billion US dollars in 2014. In 2015, however, China's foreign exchange reserves dropped to 33304 billion US dollars, i.e. around the level recorded in 2012 (Fig 3). To fight inflationist pressures, following yuan issuing, PBOC sold its own bonds to sterilize the issued liquidities (Rajan 2010, 219). Even so, China's monetary aggregate M3 increased constantly between 2008 and 2014 (Fig 4).

The evolution of the US dollar/yuan exchange rate indicate a strong devaluation and/or depreciation of the yuan in 1994 compared to the US dollar, which corresponds to a significant decrease of the Yuan's real effective exchange rate. Until 2004-2005, the Yuan/US dollar exchange rate remained at a constant level (around 8.3 yuan/US dollar). Since 2005 until 2015, the yuan gradually rose compared to the US dollar (Fig 5).

The evolution of the euro/yuan exchange rate also indicates a devaluation or depreciation of the Yuan compared to Euro. In 2001, 1 euro was exchanged for approximately 7.5 Yuan, while in 2007 the exchange rate was 10.5 Yuan (Fig 6). After the 2008 financial and economic crisis, the yuan rose compared to both euro and the US dollar. The real effective exchange rate of yuan, based on consumer price index, point an upward trend, particularly after 1994. Since 2008, the real effective exchange rate of yuan recorded a higher level compared to real effective exchange rates of both euro and dollar (Fig 7 and Fig 8).

For the first time after the 2008 crisis, a clear and consistent upward trend of the US dollar compared to the yuan was noticed in the second half of 2015. Moreover, in 2015, an appreciation of euro compared to the yuan was noticed, although in terms of annual averages, the yuan rose compared to euro in 2015 compared to 2014. The yuan's real effective exchange rate dropped, however, in 2015.

China's exports to the EU have risen almost six times in the last 15 years and those to the USA almost five times (Fig 12 and Fig 13). Moreover, since 2008, China became the main investor in U.S. Treasuries, outperforming Japan, and kept its position in the following years (2009-2015). Thus, in October 2015 China's holding of U.S. Treasures reached 1254.8 billion US dollar.

Not all economists believe that the Yuan has been devaluated by the People's Bank of China monetary policies. Some authors have a different construal on this type of data and evolutions. Thus, Jiawen Yang and Isabelle state:

"Since price index, including the Big Mac index, contains components which are not negotiable, and the index of wages in China is significantly lower than that in the United States, the RMB's

assessment based on the measurement of gross purchasing power parity is always higher than the rate determined on the market of negotiable products. The US trade balance deficits with China have been affected by many other factors (such as low labor costs of China, market structure and the economic sanctions of the United States) rather than the exchange rate. China's surpluses both in trade and current bank accounts are relatively small and do not indicate that the currency is undervalued. The rapid accumulation of international bank reserves by China was basically built by increases in capital flows, which are the result of key factors that are not determined by the market (such as controlling the flow of capital and preferential treatment of foreign investment (Bajeux-Besnainou 2004, 19).

Other economists consider as revealing the Chinese state's measures enforced in order to lower inflationary pressure on the yuan (Lardy 2005)[3]. Most studies (Jo *et. al* 2010) (Morrison *et al.*, 2013) (Lipman 2011), inclusively those of the IMF, reached similar conclusions: in order to gain advantages on international markets by increasing exports, the Chinese currency was substantially devaluated compared to the US dollar and also relatively to other currencies. Although in recent years, the yuan appreciated significantly compared to the US dollar, yuan is still considered significantly undervalued.

As far as we are concerned, the problem as detailed above, is a false one. The main benefits are not gained by those countries that devalue most their domestic currencies. The forced cheapening of domestic goods cannot be to the benefit of the economy nor to the Chinese people, since such policies cannot really increase competitiveness and wealth. Let's assume that a Chinese producer made a good X, which is sold on the market for 8 yuan before devaluation. Let's assume further that the US dollar/yuan real exchange rate is 1 to 4. This means that the American importer has to pay 2 US dollar (1 US dollar buys 4 yuan) for the good X. Let's suppose that, after the devaluation, the US dollar/yuan exchange rate is 1 to 8. Thus, the American importer will pay only 1 US dollar for the good X. The obvious advantage belongs to the American importer, who bought the good for half of the initial price. The losing party is the Chinese producer, even if he owns after transactions 8 yuan; each yuan is worth half than before the devaluation. (Finegold 2010). From this perspective, importing countries have not good reasons to stop, through protectionist measures, the "gifts" offered by exporting countries. Millions of American or European consumers enjoy Chinese goods at lower prices. The companies from the importing countries are also favored because they can obtain production factors at lower costs and thus gain advantages on the international markets, derived from expense discounts obtained as such.

Whatever the reasons behind this measure, currency devaluation cannot be a winning strategy to increase competitiveness and wealth. Even if the purpose is to fix the problems arising from trade deficits, or to increase foreign exchange reserves, or to cut off debts – this policy leads only to illusory benefits and ends with real economic losses.

Concluding Observations

The main goal of the current paper was to determine the economic costs of the neo-protectionist strategy of currency competitive devaluations as a government tool to stimulate exports and reduce imports. We have pointed out the elements making up the illusion of creating a solid competitiveness through currency devaluations as form of the new protectionism. Moreover, we have tried to prove that, in fact, this strategy, as subtle form of taxation, triggers significant loss, economic instability and illusive earnings through: reducing the purchase power of the citizens, subsidizing (in fact) foreign citizens, weakening productive incentives and distorting economic calculations and those arising from those which supplement this measure such as the inflation policy. We can now draw the final theoretical implications of the discussion above.

Currency devaluation is a more subtle form of taxation and redistribution of wealth to several beneficiaries and, also, a source of political advantage, i.e. bureaucratic reporting of trade surplus. But, in fact, encouraging exports through currency devaluation is, for any responsible economist – despite expectations, regulations or claimed desiderata – a form of protectionism which impoverishes the economy of the country that enforced it, rather than protects it. The allocation of such privileges

implies inflation through the expansion of money supply (we used as an illustration the well-known case of yuan devaluation) leading to the terrible effects detailed above. In the end, the country enforcing currency devaluation and, consequently, diminishing the purchasing power of the domestic currency, succeeds only to subsidize the consumption of foreign customers from the importing countries on account of lowering the income of its own citizens.

Endnotes

[1] However, greater clarity is not probably welcomed at political level, an increased degree of confusion and complexity being considered more useful. If we take into account the suggestion of Paul Heyne (1983, 711) that trade deficits are, in fact, powerful political weapons it becomes clear why lack of clarity in this respect, arising from aggregated data might represent politically an advantage.

[1] A prominent example is the case of the famous "ghost" cities from China. Each year over 20 such metropolises with huge malls are built, but there are no willing people to inhabit them (McMahon, 2013). An interesting statement on the topic belongs to the former finance minister of El Salvador and collaborator of the World Bank, Manuel Hinds, who claims that the best example of resource waste with money printing are "the ghost cities built in China, without enormous amounts of money, created by the People's Republic of China in the wake of the 2008 crisis". He also says that the "People's Bank did that, in the spirit of the Nobel Prize laureate, Paul Krugman, who promotes currency creations as the cure of all aliments" (Hinds 2013).

Abstract

The paper focuses on the analysis of economic and physical accessibility and availability of food in the Czech Republic. Food security includes three main pillars - availability, access, and utilisation. There is precisely examined the area of access to food, in terms of affordability and in terms of the possibility of physical access to food, because in the Czech Republic the physical accessibility to food is ensured through a single network of retail stores very well, economical access - affordability, however, is lower for many population groups.

Keywords: Food Security, Access, Affordability, Purchasing Power

Introduction

Food security is defined as a condition where the physical and economic access to sufficient quantities of healthy and nutritionally balanced food is provided that meet the nutritional needs and preferences of the individual for his active and healthy life. (FAO, 1996) Concept of food security is defined by three main pillars – availability, access and utilization.

Possibility of access to food for individuals is crucial in the context of their basic needs. In terms of physical access to food it is possible to analyze the density of retail network in the Czech Republic, in terms of affordability of food there is the expenditure of households on food. In the Czech Republic an average household issues for food and beverages (including tobacco) on average 20.7% of their income, households of pensioners, however, up to 27%. In the following text there is an analysis of the evolution of prices of main food commodities over time and an analysis of physical availability of food in the retail network, focusing on the stores that are in the Czech Republic economically significant market power. In this paper attention is not paid to distribution or offer of water respectively. The issue of water management in the context of food security, i.e. the possibility of access to and availability of water for the residents, addresses the entire range of studies, e.g. Strohmandl et al., 2015. Attention is within the professional research in the Czech Republic also paid to other sub-pillars of food security according to access to food and transport of foodstuffs (e.g. Musil et al., 2014 and 2015, Strohmandl et al., 2015).

Research Design and Findings

A very important part of ensuring food security is to ensure the accessibility of food to citizens of the state - to consumers. It is one of the pillars of food security, as shown in Figure 1.

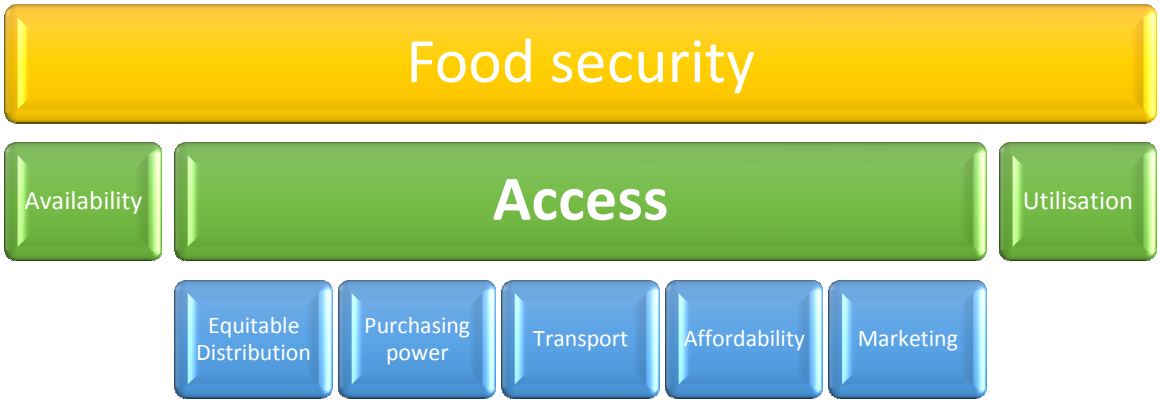

Fig. 1: Three Pillars of Food Security and Sub – Pillars of Food Access (source: India´s Water and Food Security, adapt by authors)

According to statistical data an average Czech household issues for food and beverages (including tobacco) on average 20.7% of their income, a household of pensioners but more than 26% despite the drop in food consumption. The data of food and non-alcoholic beverages expenditure for the third quarter of 2015 show that Czech household expenditures on the respective commodities are 18-24% of their income. Employed people without children issue the least - 18, 1% of their income, households with children then 18.7%. In terms of the above expenses are the most vulnerable groups of the population unemployed, pensioners and families where food expenditure shares of total spending 22-24%. The two population groups can be considered as groups that have a reduced economic access to safe food. (CSO CR, 2015) In recent years Czech consumers have changed their diet – they eat less and buy other types of food - the reason is the increasing price. In the long term the consumption of e.g. bread decreases, on the other hand the consumption of pasta, rice and potatoes in particular increases. According to developments in prices the consumption of fruits and vegetables is fluctuating (Málek et al., 2014, Lukášková et al., 2014).

Consumer food prices increased the most between 2011 and 2012, mainly due to the increase in VAT by 4%. In the given period prices of food and non-alcoholic beverages increased, compared to the EU average of more than 2.5 times. At present, prices of some food commodities are falling moderately (pork, milk, yogurt, butter), others grow (ordinary bread, vegetables and fruit) (CSO, 2016).

Table 1: Annual Change in Consumption of Chosen Foodstuff Commodities (CSO, 2013)

Commodity	Commodity Consumption in 2012	Annual Change in Consumption
Bread	41,3 Kg	- 1,1 Kg (↓)
Pasta	7,1 Kg	+ 0,4 Kg (↑)
Beef	8,1 Kg	- 1,0 Kg (↓)
Poultry	25,2 Kg	+ 0,7 Kg (↑)
Milk	57,3 l	+ 1,3 l (↑)
Eggs	245 pcs	- 9 pcs (↓)
Non-Alcoholic Beverages	278,0 l	- 9,0 l (↓)
Alcoholic Beverages	175,2 l	+ 6,4 l (↑)
Of which: Beer	148,6 l	+ 0,6 l (↑)
Wine	19,8 l	+ 0,4 l (↑)
Spirits	6,7 l	- 0,2 l (↓)

Another part of the research was to assess the status of the second sub-pillar of food security and physical access to food. There was conducted the survey of grid density of individual retail chains –

Albert (supermarket, hypermarket), Billa, Enapo, Globus, Lidl, Kaufland, Penny, Tesco. Results are shown in the following figures, where cartographic visualization was used (Fig. 2 – 4). Methods used for the spatial visualization were adapted from the thematic cartography (Slocum, 2010). We used ArcGIS for further analysis according to principles of regional development described e.g. in Trojan (2012).

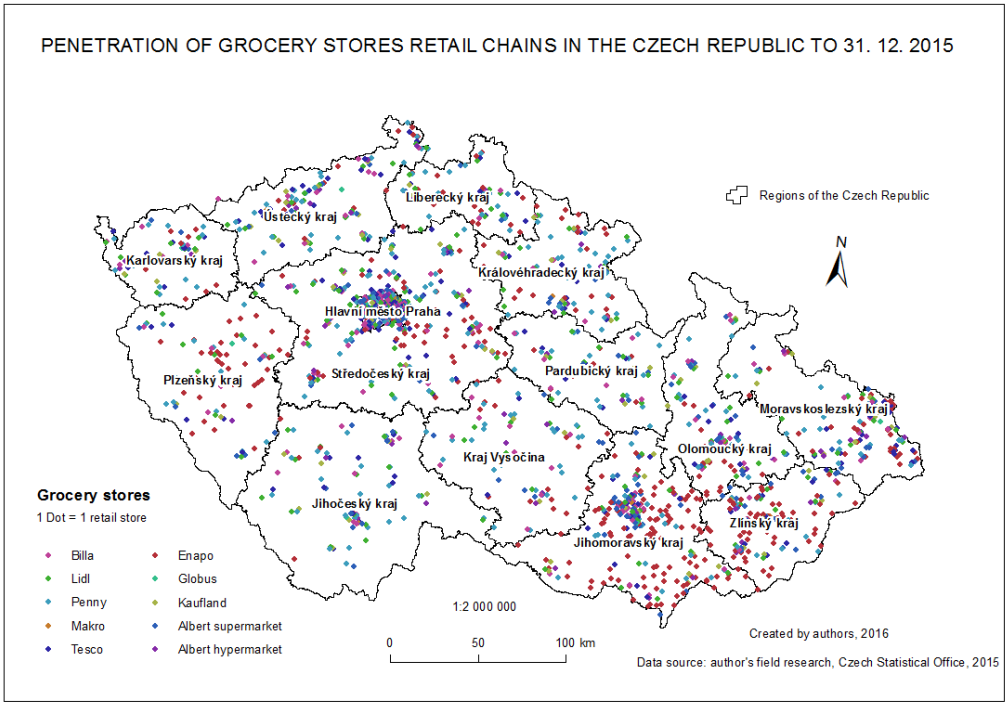

Fig. 2: Penetration of Grocery Stores Retail Chains in the Czech Republic to 31. 12. 2015

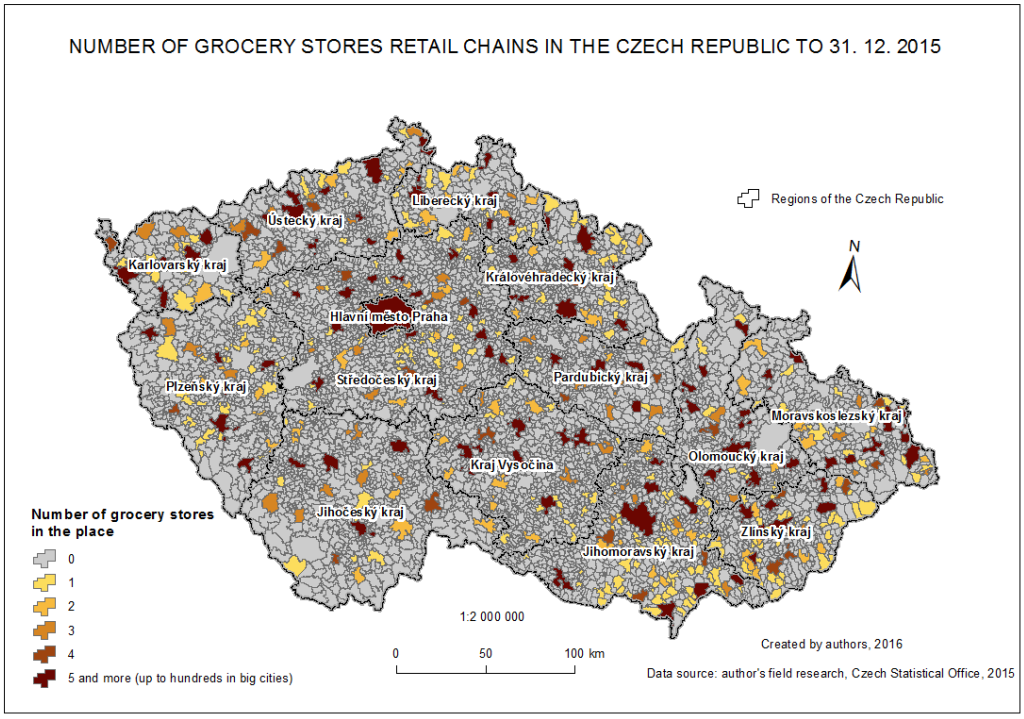

Fig. 3: Number of Grocery Stores Retail Chains in the Czech Republic to 31. 12. 2015

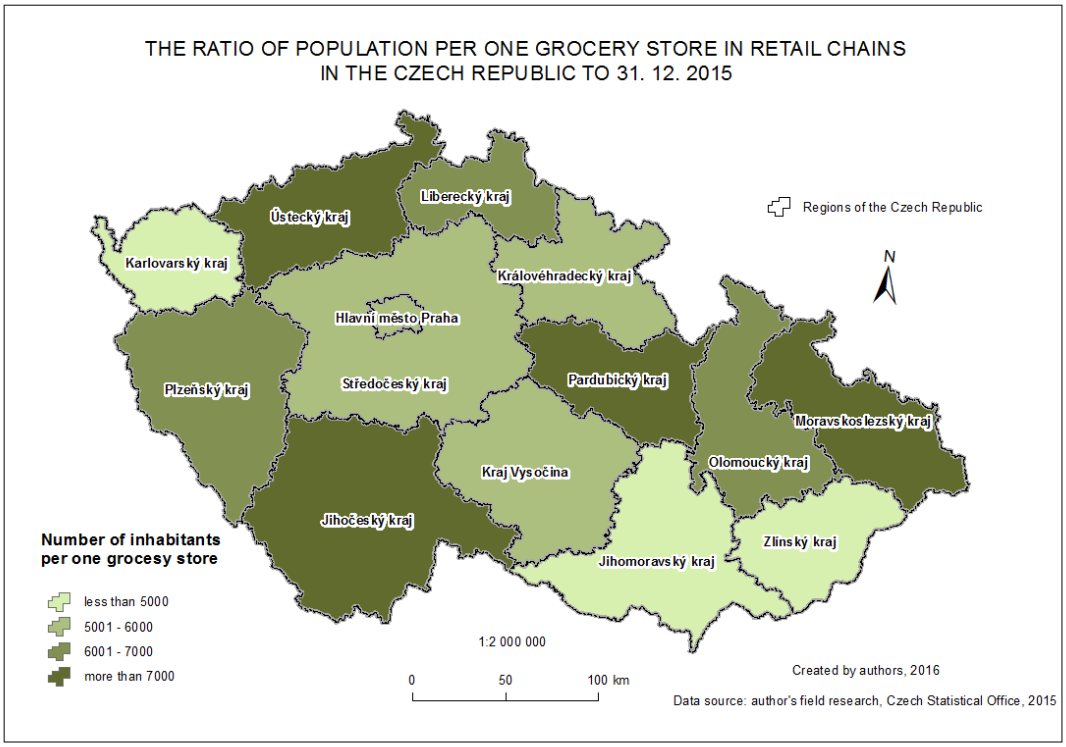

Fig. 4: The Ration of Population per one Grocery Store in Retail Chains in the Czech Republic to 31. 12. 2015

Conclusion

In the paper there was evaluated economic and physical access to food for the population in the Czech Republic. Based on the research results it can be stated that the physical availability of food is not a problem, mainly because of a dense network of retail chains in the country. In recent years, fluctuating value of economic access to food, which can be assessed both in terms of the amount of food prices and in terms of the volume of funds released for various household types of total expenditure on food consumption and non-alcoholic beverages. Significantly worse situation in terms of economic access to food occurred in the years 2011 and 2012, in particular because of the combination of rising food prices (and increased VAT on food) and also because of lower income situation of households due to the deceleration of economic recession. At present, mainly because of the increasing performance of the Czech economy which is accompanied by a decrease in unemployment and low inflation, the economic household access to food increases. That is documented in the above statistics.

Abstract

The article deals with logistics service territory. Presents logistical needs service territory. Technology presents logistic service territory. Discusses the choice of transport mode, and optimization service. It represents the state of development of logistics services in the territory of the Czech Republic.

Keywords: area, logistics, logistics center, service, territory, transport

1. Introduction

The transport sector is one of the important areas of the national economy, which affects virtually all areas of public and private life and business. It is a financially very demanding sector, on the other hand, it is a sector that contributes significantly to the revenue side of public budgets. It is a sector which is a prerequisite for increasing the competitiveness of the Czech Republic (*Nařízení Evropského parlamentu a Rady (ES) č. 1370/2007*).

Transport policy sets out what the state and its executives in transport must be made (international bond contracts) wants to do (security, sustainable development, economics, environment, public health) and can make a (financial and spatial aspects) *(Nařízení Evropského parlamentu a Rady (ES) č. 1370/2007).*

The European Union nearly 40 years after it adopted a new regulation for public services in road and rail transport - Regulation of the European Parliament and Council Regulation (EC) no. 1370/2007. Although the regulation applies directly, in the Czech Republic in relation to him, the law on public passenger transport services. The aim of the Act was a complex arrangement of public transport in one piece of legislation. Law applies to the adaptation of the Regulation sets out the conditions for the liberalization of public transport. United in that direction both modes. It is not a creation of conditions for the equivalence of different modes of transport, the possibility of linking the transport of individual Member States of the European Union, to open the market for transport services, to create conditions for free movement of goods and people and the exercise of the right of citizens to have a transport system.

2. Transport service

Transport infrastructure means ensuring the transport on all days of the week mainly to schools and educational institutions, the public authorities, to work, to health facilities providing basic health care and to meet the cultural, recreational and social needs, including return transport, contributing to

sustainable territory development (*Zákon č. 194/2010 Sb., o veřejných službách v přepravě cestujících a o změně dalších zákonů*).
Interest and duty of the state is to ensure conditions for transport services across the country. This also applies to less populated regions. Thus, the State ensures the conditions for the functioning of the article contact trade with the customer. Were this not so, there could also:

- the growth of unemployment, insecurity of supply and distribution of goods and materials for the operation of the business,
- outflow of labor force outside the region, higher demands on transport services transport to work,
- outflow of people from the region where it is accessible supplies and more jobs,
- decay and dissolution of municipalities.

Disintegration of the system of public transport due to board cuts would be negatively reflected both in the problems of "performing" transport areas (congestion, accidents, and overall increase externalities), and in other societal areas.

Definition of public transport in Act 194/2010 Coll. ensures the maintenance of public transport system in the Czech Republic, which contributes to social cohesion and regional development in the Czech Republic and regions. Transport services, the notion of Regulation (EC) no. 1370/2007.
Transport service is further defined by the specific purpose specification of individual transport modes. Individual transport implemented within public transport must ensure the availability listed in the law of public institutions, equipment or supplies to the public, every day of the week. Institutions, facilities and public needs stipulated by law must be made available to citizens by public transport always that it was the traffic on the territory (*Dopravní politika České republiky pro období 2014-2020 s výhledem do roku 2050).*

Besides the aforementioned institutions and facilities can be made available by public transportation and others not mentioned in the definition of the institution or facility. From this perspective, it is necessary to operate the territory considered as an integrated logistics system in which is included:

- transport of goods and materials,
- sorting services to the operation of the internal transport system,
- operation of warehouses and business networks,
- transport service enterprises on the side of the supply and distribution side of their goods,
- a system of basic transport services with the provision of transportation needs for purchases of goods.

The establishment of the logistics system only on a private basis is not possible. It must also provide support from public budgets:

- construction of a logistic service center (from the state budget, counties or municipalities),
- maintenance and operation of transport networks,
- operation and logistics services offered in the public interest.

Providing such support must be based on legislation.

3. Technology logistics service region

The region is a defined area which is in some way tied to certain ties to the center, which is able to provide the required type of logistics service. Regions by type of content and logistics service can be arranged hierarchically to the regions:

- local (basic),
- national (main),
- multinational (global).

Generally, technology and logistics service area referred to as a "Hub and Spoke". The essence of existence is one center (Hub) that receives or dispatches large shipments, assembles or disassembly of and radial (Spoke) operates a defined territory. A place in which to conduct operations defined as logistics services are called logistics centers. Function of logistics centers is mainly adopt consolidated shipment size from one transport or transport unit disassembly of bulk shipments arranged by the directions of the target beneficiaries and ensure their preparation for transportation from city customers, collect consignments exported from the region and create sets of them directional, directional tell shipments designed either direct customers or other logistics centers, storage and material goods as a public repository, providing users the additional transport services, securing the extent of its premium services, brokerage customs clearance, especially as regards the transnational region (Global) type.

Logistics center as a main activity does not create long-term stocks. Goods stored only for a temporary period of several hours, which derives from technology assembly and disassembly. This is a so-called flow store.

4. External and internal transport system

Utility transport system is divided into two areas:

- external transport system which caters transport links with other logistics centers, and suppliers of goods entering the region or with purchasers of goods that the region exports, shipments transported outside the transport system are mainly large volume and directionally arranged input and output,
- internal transport system that ensures delivery of shipments disassembly of arrow to the target recipient (for example, retail, retail store, warehouse enterprise.
-

External transport system mainly uses high-quality infrastructure and capacity and a corresponding mode

of transport. In the Czech Republic it is mainly about:

- rail, implemented at the national railways, usually at the logistics center connected siding,
- road transport, carried out in road capacity means,
- a combination of rail and road transport in an integrated (pallet or container) system, which requires appropriate technical equipment for handling containers or pallets inside the logistics center,
- inland waterways, but in the Czech Republic is used minimally (*Zákon č. 114/1995 Sb., o vnitrozemské plavbě, ve znění pozdějších předpisů).*

The internal transport system that ensures the collection and distribution of goods in the region is based on road transport and is carried out by means that are adapted:

- average weight of consignments,
- traffic restrictions corresponding to the type of communication (roads of various classes) and the requirements for compliance with environmental standards (for example, in the centers of some towns, in some European countries).

5. Election mode and optimization service

Modal choice in external and internal transport system depends primarily on:

- characteristics of the consignment and its transport properties,
- the nature and level of transport infrastructure,
- legislative framework for the various modes of transport,
- safety requirements,
- administrative constraints induced environmental protection.

Level shipment corresponds to each characteristic level of transport so that it always creates a dual level indicator shipment and shipment levels:

a) the level of shipments: defining the place of creation and destruction of transportation,
Level of transport: the determination of optimal transport routes, including for modal shift, using a multimodal transport system,

b) the level of shipments: define the size of the consignment in size and weight,
Level of transport: the selection of a suitable type of means of transport for a single shipment or transport ensemble composed of collected more shipping consignments,

c) the level of shipments: the need to speed the delivery conditional, for example, the possibility of perishability,
terms of delivery to the business, creating logistical stocks,
Level of transport: calculate the optimum transport speed by comparing costs and losses,

d) the level of shipments: reliability needs, such as supply consignments Just in Time restore stocks of individual

items automatically controlled warehouse in an optimized system,
Level of transport: the calculation of the optimal interval between deliveries and maximum permissible time deviation from the established delivery by comparing costs and losses,

e) the level of the shipment: shipments resistance against the effects of transport technologies that affect the properties of the product itself, secondly, such as toughness, fatigue, flowability, viscosity, and the like, as well the properties of the transport, container,
Level of transport: a selection of suitable transport and transport technologies,

f) the level of shipments: the need for additional services such as customs clearance, handling when changing mode of transport, or during loading and unloading,
Level of transport: the system services required. *(Pernica, P. a kol., 1998*).

Based on the comparison of dual indicators may make the optimal choice of the transport system. Subsequently examine the level of transport infrastructure. The next step is then verifies the legislative framework for the various modes of transport in the country of origin, course and termination of transportation. In selected categories of items Transportation is severely restricted or even banned. The last step is to verify the environmental and administrative measures on selected transport routes, for example in terms of standards of noise emission standards and other possible restrictions such as a ban on certain types of transport service vehicles in a certain day or night.

6. State of implementation of logistic services in the territory of the Czech Republic

Logistic service area began to emerge in the mid-nineties on a purely commercial basis, especially where it has already been built at least part of the infrastructure. Offer services resulted from the commercial interests of customers. Since 1996 have been launched, subsequent construction and development of logistics centers for servicing regional technology hub and spoke.

The basic solution was a statistical analysis of production (division-size factories and commodities) and consumption (with regard to the number of inhabitants and type of goods).
Based on the analysis of the number, size categories and spatial distribution of industrial plants and centers

of consumption in the Czech Republic have been identified as suitable sites for future logistic centers. Allocation of a network of logistics centers is continually confronted with the proposed and actual development of transport infrastructure. Also considered are the use of assumptions logistics centers

as gateways (gateways) for the logistical operation of urban agglomerations. For each city is analyzed basic assortment structure of logistics chains attached to industrial plants and anticipated demarcated areas of these centers. (*Strategie regionálního rozvoje ČR na období 2014-2020).*
We not always managed properly allocate logistic centers. The causes are in the turbulent development

of certain regions and vice versa in decline in other regions. This is related to:

- restructuring the industry,
- restructuring of agriculture,
- further depopulation in urban agglomerations,
- changes in living standards,
- changes in life values and habits,
- globalization,
- offshoring,
- the application of Schengen Convention,
- environmental protection.

Options allocation of logistics centers in the Czech Republic are places like Praha, Brno, Liberec, Plzeň, Ostrava, Pardubice, Přerov, Ústí nad Labem, České Budějovice and Tabor *(Pernica, P. a kol., 2001).*

If multinational companies operating in Europe, built its new logistics center with pan-European reach, then proposed logistics centers in the Czech Republic when exporting goods must meet the same requirements to supply products to several hours and days. It follows that the network of distribution centers must be differentiated (hierarchically structured), to:

- the main logistic centers with the best possible transport connections fast rail or road or air transport large logistics centers in major conurbations of the European Union, must be fully competitive corporate logistics centers of multinational companies and must provide superior logistics services in an unlimited extent,
- regional logistics centers are equally good transport links to the logistics centers in neighboring countries, which will lie on the same road or rail routes such as logistics centers.

7. Possible impacts on the Protection of Population

Options allocation of logistics centers in the Czech Republic can also create favorable conditions for the provision of services to the population in relation to safety. These are mainly dealing with emergencies such as natural disasters, floods, accidents and technical equipment like (*Svoboda, V., Latýn, P., 2003).*

If you build logistics centers of national companies or government, this aspect may also include the requirements for the allocation and construction. If multinational companies operating in Europe are building their new logistics center with pan-European reach, then this requirement is more difficult to promote.

Logistics centers can play an important role in dealing with emergencies. If you have the required structure and amount of material can be used to provide material assistance for emergency supplies of food and water, disinfectants, clothing, personal hygiene, cleaning and so on.

8. Conclusion

Transportation is an important area of the economy that affects virtually all areas of public and private life and business. One of the duties of the state is to ensure conditions of transport in the entire national territory. Operation area is an integrated logistics system several interdependent

processes. Logistic service area comes in several forms of general logistics. You can apply the appropriate utility transport system. Modal choice depends on several factors (*Šafarik, Z., Vičar, D., Lošek, V., Rak, J. and J., Trojan*). The decisive nature of the serviced territory. It can be a logistical operation regions demarcated area designated to some central (economic, administrative, to the settlement, and the like). In this type of service area is developed technology hub and spoke.

Logistics operator in the Czech Republic is developing and so is the territory of another type of big cities, which have a number of traffic restrictions for reasons of traffic flow in city roads, building density and environmental reasons. These territories will create systems collectively term "city logistics" and largely applied logistic Gateway technology.

And in Europe exists another type of territory, which we refer to as agglomeration, which could be described as an intermediate step between the region and the city. That is, it has strong core center to which they are economically or socially bound surrounding villages, housing estates and residential satellites. It does not reach the dimensions of the region and the operator assumes certain specifics of both previous types. For agglomerations it is necessary to create individual physical and organizational architecture and instructions take into account the diffusion of passenger and freight transportation on a common infrastructure.

Logistics centers can play an important role in dealing with emergencies. If you have the required structure and amount of material can be used to provide material assistance for emergency supplies of the population.

Abstract

Presenteeism behaviour continues to be a common issue at the workplace. This has resulted in various organizational problems, including loss of productivity at work. Thus, this paper is aimed to investigate: (a) work-related factors related to presenteeism among academicians at public universities, and (b) the association between work-related factors related to presenteeism and work productivity. This research study was conducted at the selected public universities in the East Coast region of Peninsular Malaysia. Respondents consisted of 194 academicians from three selected public universities. Data were obtained and gathered through the distribution of questionnaires to respondents. Descriptive statistics revealed that 61% respondents were female (61.3%) academicians with aged range of 30 – 39 years (33.5%). Most of them were married (70.6%) and work as permanent staff (64.9%) of the public universities. In correlation analysis, the study findings revealed that there was a significant positive relationship between work-related factors (job demand ($r=0.31$; $p<0.01$) and time pressure ($r=0.22$; $p<0.01$)) and the frequency of presenteeism in public universities. Academicians with high level of job demand were found to have high tendency and were more inclined towards attending at work while ill. In conclusion, the frequency of presenteeism could be reduced if the health status were improved. However, job demand and job security factors related to presenteeism predict the work productivity. An improvement should be made for future study in investigating the person-related factors relating to presenteeism in varying professions.

Keywords: Presenteeism, job demand, job security, time pressure and work productivity

Introduction

The prevalence of presenteeism continues to rise within the organization. Presenteeism occurs when employees are physically present at work, nonetheless their concentration is absent (Gilbreath & Karimi, 2012). Hirsch and colleagues (2015) emphasized that employees who are at work, but their mental energy is not devoted to their work can be considered as presenteeism behaviour. As Hansen & Andersen (2009) believed that an employee who is still present at work at the appointed time needs to be at home, due to health conditions, thus less productive at work. Many studies found that work productivity is one of the consequences of presenteeism behaviour (Scultz and Edington, 2007; Johns, 2010; Ospina, 2015). Several studies that investigating presenteeism behaviour were targeting various working adults, including office workers, nurses, computer workers, however, academics in

higher institutions was scarce (Scultz and Edington, 2007; Karimi, Cheng, Bartram, Leggat and Sarkesshik, 2014).

In Malaysia, the internationalization of higher education sector is a high priority for the government. Thus the Malaysia Education Blueprint (Higher Education) 2015-2025 was launched with the aim to produce holistic and balanced graduates with an entrepreneurial mind. The academicians are required to stay open to and adopt these new ways of working, to work collaboratively with all the stakeholders during the transformation journey. In addition, academics are urged by the industry and the policy makers to transform their traditional role of teaching and research by adding an additional pivotal role in economic regional development (Khairunneezam, 2011). This has resulted in a more sophisticated job design in an academic setting. Therefore, it is crucial to address the presenteeism behaviour among employees, particularly academicians as the nature of complexity academic work.

From the best of the author's knowledge, few studies were found investigating the contributing factors of presenteeism, in particularly targeting academicians (Ospina, Dennett, Waye, Jacobs, & Thompson, 2015; Johns, 2015; Schultz & Edington, 2007). This paper therefore attempts to investigate 1) the work-related factors of presenteeism among academics of public universities in Malaysia and 2) the association of work-related factors of presenteeism and work productivity.

Literature Review

Presenteeism behavior has variously described, which sometimes considered as well, however, it regards as obsessive when relates to employees's health and productivity (Johns, 2010). The presenteeim affects the health status as the employee is physically present, but is mentally absent. In other words, the employee is at the workplace, but their cognitive energy is not devoted to their work (Gilbreath & Karimi, 2012). The situation happens when the employee is not in good health condition, but still present at work in appointed time. Despite the health is worsening, present to work while ill gives the consequences on low productivity rate (Johns, 2010; Cooper, 1996).

In a research study conducted by Taifor, Abdullah & Hashim (2011) has found that presenteeism may cause the productivity loss as the employees have limited ability in completing tasks due to poor health conditions the employees experienced on. Apart from that, presenteeism carries a negative work environment, where the workers do not give full attention to their work (Johns, 2010). This may make the workers be less productive, commit more mistakes and produce a low quality of service compared to usual circumstances.

Presenteeism highly occurs among employees in the public sector due to the sense of high responsibility towards their clients which is welfare or service sector and especially the education area (Caverley et al., 2007; Aronsson, Gustafsson & Dallner, 2000). Meanwhile Aronsson, et al., (2000) found that employees in healthcare or welfare service or in teaching occupations have a substantially increased in number for being at work while ill. Consistently, a study conducted by Cocker et al., (2011) pointed out that professions which require voluntary actions, teaching, and job that demands for his/her assistant responsibilities like client, colleagues are strongly associated with presenteeism and productivity.

According to Aronsson & Gustafsson (2005), general health status is considered a prerequisite to presenteeism. They also suggest the act of presenteeism with the work and personal factor as the main antecedents contributing to presenteeism. Moreover, gender had been correlated with absenteeism and presenteeism (Claes, 2011). A study by Laaksonen, Martikainen, Rahkonen & Lahelma (2008) revealed that women have higher absenteeism than men; where it is just the same when it comes to presenteeism. Unfortunately, contrast to Aronsson & Gustafsson (2005) finding that gender had little no explanatory value for presenteeism. Nevertheless, downsizing also caused employees in an organization to present even sick, mostly among male.

In Malaysia, the development of higher education institutions has been rapid commencing with the establishment of the first public university, the University of Malaya in 1962. The internationalization of the higher education sector has become a high priority for the government. Hence the Malaysia Education Blueprint (Higher Education) 2015-2025 was launched with the aim to produce holistic and balanced graduates with an entrepreneurial mind. The academician is required to stay open to and adopt these new ways of working, to work collaboratively with the stakeholders during the transformation journey. In addition, academics are urged by the industry and policy makers to transform their traditional role of teaching and research by adding an additional pivotal role in economic regional development (Khairunneezam, 2011).

Many studies showed that various factors contributing to the prevalence of the act of presenteeism, including work-related factors (Johns, 2015; Schultz & Edington, 2007). Some of work-related factors that might associate with presenteeism were job demand, time pressure, job insecurity, replaceability and organizational commitment (Taifor et al., 2011; Johns, 2011; Collins & Cartwright, 2012; Claes, 2011; Aronsson & Blom, 2010; Hansen and Andersen, 2008; Aronsson & Gustafsson, 2005). Johns (2011) also carried out a study examining the factors and connection between presenteeism and productivity loss. Time pressure, control over work tasks, relationship with colleagues and employment conditions are among the work-related factor discovered (Hansen and Andersen, 2008). Ferreira and collegues (2010) revealed that presenteeism behavior reduced work productivity by 33%. Three common health conditions, namely obesity, depressive symptoms, and smoking, adversely affect the work productivity of high school employees (Alker et.al. 2015).

In line with the objectives of this paper, several research questions have been formulated. The research questions are described below.

RQ 1: What are the work-related factors of presenteeism behaviour among academics at the selected Public Universities at East Coast, Malaysia?

RQ 2: To what extend the associations between work-related of presenteeism and work productivity in the selected Public Universities at East Coast, Malaysia?

Methodology

Design and Procedure

The present research study can be considered as a descriptive and correlation research design. A cross-sectional method was used for data collection technique. In order to ensure the high return rate, several follow-up strategies were carried out. The target population of this study was academicians from public universities. However, only three public universities were selected in accordance with the established criteria. Data collection was carried out in the East Coast, Malaysia. Prior to data collection, approval was obtained to conduct the research study from the selected public universities. In estimating a sufficient sample size, the process of stratification initially conducted and followed by random selection of subjects. Disproportionate stratified random sampling was used in estimating the sample size since the different universities did not have the same sampling fractions as each other.

Data collection

A structured survey question was distributed to a total of 330 respondents through email. Of the total, 204 questionnaires were completed and returned. It is equivalent to 62% rate of response. Using guidelines from the American Association for Public Opinion Research (APPOR, 2011), a response rate of 60% and above is considered acceptable. However, only 194 questionnaires were valid for data analysis purposes. A survey questionnaire was used and adapted from established questionnaires in previous studies (Aronsson et al., (2011); Klandermans, Hesselink & Vuuren, (2010); Caverley et

al., (2007); Aronsson & Gustafsson, (2005). Overall, the questionnaire has four sections with 38 items.

Statistical Analysis

The descriptive and inferential statistics were employed in this study. The descriptive statistics included mean, frequency, standard deviations, variance and range. Bivariate analysis was used to investigate the correlation between the variables in this study. Regression analysis was also employed to predict work productivity from the work-related factors in relation to presenteeism. Data obtained was analysed by Statistical Package for Social Science (SPSS) version 22.0.

Results and Discussions

Demographic Profile

The demographic profile of the respondents includes gender, age, marital status, employment status, highest educational background, job tenure and university. Data findings of the demographic profile and background are described in Table 1. The study findings showed that more than half of the respondents were female (61.3%, n=119) and 38.7% (n=75) were male. Sixty-five respondents (33.5%) were aged between 30 – 39 years old and nearly 30% (n=57) were aged 23 – 29 years old. Meanwhile, 18% (n= 35) of the respondents were in the range 40 – 49 years old. Less than 20% of the respondents aged 50 – 59 (12.9%) and 60 – 69 years old (6.2%). The majority of the respondents were married (70.6%, n = 137), while, 26.3% of the respondents were single (n=51) and only 3.1% (n=6) were others status.

Table1: Demographic Charateristics of Respondents (N=194)

Demographic characteristics		Frequency (n)	Percentage (%)
Gender	Male	75	38.7
	Female	119	61.3
Age	23-29	57	29.4
	30-39	65	33.5
	40-49	35	18.0
	50-59	25	12.9
	60-69	12	6.2
Marital status	Single	51	6.2
	Married	137	70.6
	Others	6	3.1
Employment status	Permanent	126	64.9
	Contract	60	30.9
	Others	8	4.1
Job Tenure	Less than 3 years	68	35.1
	3 – 7 years	58	29.9
	8 - 12 years	34	17.5
	More than 12 years	34	17.5
Highest education	Ph.D	53	27.3
	Master Degree	122	62.9
	Bachelor Degree	19	9.8

University	University A	71	36.5
	University B	55	28.4
	University C	68	35.1

Demographic variables fall into the first category. The results showed that older employees were found to be more likely to attend work while sick with average age 30-39 were likely to attend work while ill. According to Hansen & Andersen (2008), presenteeism and age are positively correlated. The study findings showed that female (61.3%) respondents are more than half compared to men and have higher intentions for presenteeism (77.8%). This has resulted in women put more effort into family life and child care. However, Nyberg and colleagues (2008) found that in a hospital setting, men seem to be more prone to presenteeism as compared to married women. This supports the findings that the employees with dependent children are more likely to experience presenteeism (Aronsson et al., 2000).
In relation to employment status, more than half of them were permanently employed (65%, n=126). While 30.9% (n= 60) of the respondents were on contract basis and the remaining of 4.1% (n=8) was employed with other status.

In terms of working experience, 68 (35.1%) respondents had been working for less than three years and 58 (29.9%) had worked from three to seven years. Meanwhile, 34 respondents (17.5%) had been working from eight to twelve years and another 17.5% (n= 34) worked for more than twelve years.
Based on the Table 1, there are 62.9% (n= 122) respondents had master degree, PhD were 27.3% (n= 53) and another 9.8% (n= 19) were degree holder. It was reported that 40% (n= 71) of the respondents represented University A, 35.1% (n= 68) University C and the remaining 28.4% (n= 55) were University B.

According to Aronsson & Gustafsson (2005), health conditions of employees act as preliminary requisite in the act of presenteeism behavior among employees. Table 2 tabulates the findings related to health of the respondents. It was found that the majority of the respondents have a good health status (44.8%). It was followed by fair health status (30.9%), very good (11.3%), poor (8.2%) and excellent (4.6%). The health conditions of the respondents also had been analyzed. The results show that most of the respondents (30.4%) experienced an acute illness like fever and cough, flu and dizzy followed by arthritis or joint pain (22.7%). However, a systematic review conducted by Scultz and Edington (2007) found that health conditions such as allergies and arthritis are associated with presenteeism. In a recent study conducted by Johns (2015) found that although many medical conditions have been associated with reported productivity loss, the most prominent correlates include allergy, arthritis, depression, migraine, and musculoskeletal and respiratory problems.

Table2: Health status and conditions

Level of Health		**Frequency (n)**	**Percentage (%)**
General Health Status	Poor	16	8.2
	Fair	60	30.9
	Good	87	44.8
	Very good	22	11.3
	Excellent	9	4.6
Health Conditions	Common illness	59	30.4
	Arthritis or joint pain	44	22.7
	Asthma	21	10.8
	Back or neck disorder	37	19.1
	Breathing disorder	12	6.2
	Depression and anxiety	25	12.9
	Diabetes	21	10.8
	Migraines	34	17.5

Stomach or bowel	26	13.4
disorder	22	11.3
High blood pressure	13	6.7
Allergies	7	3.6
Heart – problem	13	6.7
Others		

Frequency of presenteeism is shown in Table 3. Majority of the respondents (77.8%) had the intention to be present while ill. It was also reported that most academicians of public universities in the East Coast Malaysia experienced presenteeism. Table 3 depicts that nearly 40% of academicians had episodes of presenteeism two to five times, while almost 30% had done so more than five times in a year. Only 16% of academicians had no experience of presenteeism and 17% had experienced it once. In a nutshell, 84% reported the act of presenteeism among academicians of public universities in the East Coast Malaysia.

Table3: Frequency of presenteeism (N=194)

Presenteeism		**Frequency**	**Percentage**
Intention to Presenteeism	Yes	151	77.8
	No	43	22.2
Experienced of Presenteeism (A year)	Never	31	16.0
	Once	33	17.0
	Two to five	76	39.2
	More than five	54	27.8

Presenteeism is prevalent in jobs where attendance has a great influence on other people and on their primary needs (Aronsson et al. 2000). The present study indicated that 39% of the presenteeism occurs 2 to 5 times a year and higher health reason for presenteeism is an acute illness like fever and cough (34%). The paves way for presenteeism is nature of academics itself which requires working closely with the students and the tasks mostly cannot be postponed or delegated. Moreover, Caverley et al. (2007) suggested that the decision to be at work despite being sick is related to replacement and responsibilities. Thus, in consistent with academics setting, the replacement is impossible and the sense of responsibility must be present to ensure the daily activities run smoothly.

The present study findings revealed that the act of presenteeism (84%) occurs among academicians. Among them, 31% were on contract basis. Job demand was also discovered as the most contributing work-related factor of presenteeism among academicians. Similar to a study conducted by John (2011), employees may come to work while ill so as to maintain their work performance. High job demand occurs when they are employed on fixed-term contracts and expected to achieve a permanent status later on (Caverley et al, 2007).

Summary of mean and standard deviation of the variables is presented in Table 4. Respondents rated their work productivity and work-related factors, including job demand, time pressure, job security, replaceability and organizational commitment. These constructs were measured using the five-point Likert scale format ranging from totally disagree to totally agree. Most of the means score for each item were below the scale of 4.00. All the standard deviation values were between in more likely narrow ranges. However, respondents rated their agreement with the statements as agreed for several items. The statements were shown in the Table 4. The work-related factors that influence preseteeism behavior were examined. Data findings showed the respondent agreed that job demand (M=3.86, SD=0.73), replaceability (M=3.63, SD=1.00) and time pressure (M=3.59, SD=0.92) were contributing factors of presenteeism. While the respondents assumed job security (M=3.28, SD =1.08) was not certain as a contributing factor of presenteeism.

Table 4: Mean and standard deviation of work related factors and work productivity

Construct	Statement	M	SD
Job demand	*Do you have to rush?*	4.05	0.79
	Do you have too much work to do?	4.13	0.84
	Do you have to work extra hard to finish a task?	3.90	0.85
	Do you work under time pressure?	3.73	0.94
	Do you have to work fast?	3.52	1.02
Time pressure	*I need to bring my work to home.*	3.71	1.11
	I often skip my breakfast and lunch.	2.54	1.25
	Sometimes I feel that I am not able to finish up my work during work hours.	3.52	1.11
	I often go home late because of having too much work.	3.51	1.29
Job security	*I am worried very much about becoming unemployed.*	3.38	1.40
	Loosing a job is very serious for me.	3.83	1.27
	The chances of losing my job are very high if I did not come to work.	2.93	1.26
	I am worried that I might lose my job if I did not come to work.	2.99	1.32
Replaceability	*I am inclined to attend to the job even though I am sick since I know the work is piling up.*	2.56	1.24
	It can be difficult to find someone else to take over and perform my work in my absence.	3.65	1.17
	I able to adjust my work by completing the most necessary work tasks and postpone the rest when I sick	3.61	1.12
Organizational commitment	*I am willing to put in a great deal of effort beyond normally expected in order to help the organization be successful.*	4.24	0.66
	I feel very little loyalty to this organization.	1.98	1.02
	This organization really inspires the best in me in the way of job performance.	4.05	0.75
	I really care about the fate of this organization.	4.22	0.72
Work Productivity	*Because of my health condition is not so good, the stresses of my job were much harder to handle*	3.24	1.12
	Despite of my health condition is not so good, I was able to complete difficult tasks in my work	3.36	1.03
	My health condition distracted me from taking pleasure in my work.	3.43	1.27
	I felt hopeless about finishing certain work tasks due to my health condition	2.87	1.12
	At work, I was able to focus on achieving my goals despite with my poor health condition	3.19	1.08
	I felt energetic enough to complete all my work.	3.13	1.19

M = Mean & SD = Standard deviation

Correlations

A bivariate correlation analysis was conducted to investigate the relationships between health status and frequency of presenteeism behaviour. The study results reported that there is negative relationship between health status and presenteeism ($r= -0.15$, $p<0.05$) among academics in the public universities.

Nevertheless, Lerner, Amick, Malspeis, & Rogers (2000) found that nearly one-third of adults with chronic health problems reported recent moderate to severe difficulty on the job in at least one of three areas. As number of conditions increased, so did odds of having a work limitation. In addition to that, in a research conducted by Van den Heuvel and colleagues (2010) found that poor general health and longstanding health conditions were associated with productivity loss.

A correlation analysis was also conducted to examine the relationship between frequency of presenteeism and the work-related factors; including job demand, job security, replacebility, time pressure and organizational commitment. Moreover, the association between work-related factors and work productivity was examined.

Table 5: Pearson correlation analysis

	Variables	1	2	3	4	5	6
1	Job demand						
2	Time pressure	.639**					
3	Job security	.206**	.293**				
4	Replaceability	.218**	.129	.028			
5	Organizational commitment	.333**	.202**	.124	.144*		
6	Frequency of Presenteeism	.310**	.224**	.085	.049	0.021	
7	Work Productivity	.201**	.086	.202**	-.031	0.094	0.122

***p< 0.01; *p<0.05*

As shown in Table 5, data findings indicated that job demand ($r = .310$, $p<0.05$) and time pressure ($r = .224$, $p<0.05$) have a significant positive relationship with frequency of presenteeism. Nevertheless, there was no significant relationship between replaceability and frequency of presenteeism among academicians ($r = .049$, $p>0.05$); job security and frequency of presenteeism ($r = .085$, $p>0.05$); and organization commitment and presenteeism ($r = .021$, $p>0.05$). Data findings also reported that job demand ($r=.201$; $p<0.01$) and job security ($r=.202$; $p<0.01$) were significantly correlated to work productivity. This data findings were supported by Quazi (2013), in which pointed out work-related factors contributing to sickness presenteeism include job demands, job security, and replaceability. According to Aronsson & Gustasson (2005), time pressure was also a contributing factor to presenteeism.

A linear regression was conducted to examine if the contributing work-related factors predicted the level of work productivity among academics in public universities, particularly in East Coast, Malaysia. The contributing factors of preseteeism were examined. Details of linear regression analysis are shown in Table 7. Using the enter method, it was found that the contributing factors of job demand, time pressure, job security, replaceability and organizational commitment explain a significant amount of the variance in the level of work productivity ($F(5, 188) = 3.374$, $p < 0.01$, $R^2 = 0.287$, R^2Adjusted = 0.058). The prediction model was only accounted for approximately 28% of the variance of work productivity.

Table 7: Multiple Regression Analysis for Work-related Factors of Presenteeism Predicting the Work Productivity of the Respondents (N = 194)

Variable	*B*	*SEB*	β
(Constant)	1.985	.539	
Job demand	.315	.119	.252**
Time pressure	-.125	.094	-.124
Job security	.156	.062	.186*
Replaceability	-.071	.065	-.078
Organizational Commitment	.038	.120	.024

Note: *R^2=0.287, R^2 Adjusted = 0.058, F (5,188) = 3.374, p=0.006, *p<0.05; **p <.001*

The data findings shows that the factors of job demand (Beta 0.252, t(193) = 2.64, p = 0.009) and job security (Beta = 0.186, t(193) = 2.54, p = 0.012) did significantly predict the level of work productivity among academics of public university in East Coast, however replaceability (Beta = -0.078, t(193) = -1.088, p>0.05); time pressure (Beta = -0.133, t(193), = -1.35, p > 0.05) and organizational commitment (Beta = 0.024, t(193), =0.317, p > 0.05) did not significantly predict the work productivity among them. Overall, the job demand is the most contributing work-related factor of presenteeism that influence the level of work productivity.

The present study revealed that job demand and job security influence the level of work productivity among academicians in the public universities. This is supported by a recent study conducted by Johns (2015) suggests that heavy job demand is one of variables motivates presenteeism and consequent productivity loss incurred. Consistently, in a study by Cooper (1994) suggested that presenteeism is crucial since it does not just affect one person but the rest of the organization, in which it increases cost, yet reduced the work productivity as well as the quality of work. In contrast, Collin & Cartwright (2012) found that time pressure and insufficient work resources had impacts on presenteeism and productivity. When there is scarcity of resources, it generates extra costs and give real negative impact on workforce morale as other people have to pick up more and more work. It can be suggested that is the reason why lost productivity from presenteeism is at least three times higher than from absenteeism. In addition, the employees themselves exaggerating their illness and becoming worse when the illness is pandemic. The challenge for the federal government or policy maker is a major culture and thinking shift. In order to reduce the presenteeism occurrence, preventive measures should be taken.

Excellent management of presenteeism can lead to productivity improvement, increase in employee motivation, loyalty and enhancement of employer branding. Morever, when employers focus on presenteeism as an important part of healthcare benefits, their employees' health can be transformed from a cost burdened to competitive advantage.

Conclusion

The results of the study provide an awareness among academicians regarding the phenomenon of presenteeism as it gave an impact toward their productivity. It is becoming a very challenging for an organization to maintain a healthy and productive employees. The findings show a majority of the respondents had the intention to be present at work while ill. The study found that there was a significant positive relationship between work-related factors and the frequency of presenteeism in public universities. It is evident that work-related factors contribute to presenteeism including job demand, job security, replaceability and time pressure. An improvement should be made for future study in investigating the organizational behavior relating to presenteeism. Therefore, future research should examine the relationship between presenteeism and person-related factors.

Abstract

Within the context of public health protecting in the Czech Republic, the key law is the the law no. 258/2000 Coll.: "On protection of public health and amending certain related laws, as amended". To Human health is important to ensure quality and safe drinking water. The most important and comprehensive European Union's legislation is Water Framework Directive (2000/60/EC) of the European Union, which applies to all waters. The Czech Republic's or eventually European Union's population health status is influenced by a quality of drinking water, and water used for various purposes as well. The water is polluted by various substances, including remnants of drugs. The presented professional contribution is focused precisely on this subject, including some basic legal standards.

Keywords: European Union, Czech Republic, risks, drinking water, public health

Introduction

Act no. 258/2000 Coll. On protection of public health and amending certain related laws, in its basic concepts defines, among others, the notion of public health, public health risk assessment and more.

For human health is important to ensure safe drinking water. (*Rak Jakub, Jurikova Lucie, Sevcik David 2013).* Now mentioned Law on Protection of Public Health states that drinking water is all water in its original state or after treatment, which is intended for drinking, cooking, preparing food and drinks, water used in food industry, water, which is designed to body care, cleaning objects which by design come into contact with food or human body, and for other purposes of human consumption, regardless of its origin, state and manner of its delivery. Hygienic requirements for safety and purity of drinking water (hereinafter referred to as " the quality of drinking water ") is determined by hygienic limits of microbiological, biological, physical, chemical and organoleptic characteristics, which are regulated by the implementing regulation. *(Zákon č. 258/2000 Sb., o ochraně veřejného zdraví a o změně některých souvisejících zákonů). (Strohmandl Jan, Weinbergerova Silvie, Masek Ivan, Safarik Zdenek a*nd *Miroslav Tomek. 2015). (Strohmandl Jan, Tomek Miroslav, Masek Ivan and Taraba Pavel. 2015*). In terms of the European Union represents the Water Framework Directive (2000/60/EC), dated 23 October 2000, the most significant and comprehensive legislation in the area of water. The Water Framework Directive covers all waters - inland surface water, groundwater, transitional and coastal waters. Establishes the principle of a Europe-wide integrated approach for issues related to water quality and quantity, and regarding the issues of surface water, groundwater and for the water management the Directive introduces a management principle based on the unit of the river basin - in the Czech Republic this principle is implemented since the 60s of the last century. Water is therefore considered as a coherent whole. The primary objective of this policy is to achieve a "good status". *(Směrnice. Vodní rámcová směrnice 2000/60/ES).* To protect the population need to secure clean water. If this is not possible, then deal

with emergency supply residents with water. *(Musil Miroslav, Ludek Lukas a kolektiv. 2014). (Rak Jakub, Vicar Dusan, Tomek Miroslav, Svobodova Blanka 2015).*

Health and hygiene risks of water and the impact on public health

One of the problem areas that occurred in relation to the issue of drinking water in the Czech Republic are the remnants of pharmaceuticals in drinking water. Due to the reports of a possible presence of residues of pharmaceuticals in drinking water in the Czech Republic , which appeared in the media, the National Health Institute made its first horizontal mapping of pharmaceuticals in drinking water. In this first population-based screening of human pharmaceuticals in drinking water, carried out in 2009 - 2011 in a research project of GACR. „Occurence and health risks from human pharmaceuticals residues in drinking water ", five active substances were followed: naproxen, ibuprofen, diclofenac, carbamazepine and 17α - ethinylestradiol.

The substances were selected according their consumption greatest probability of occurrence based on the foreign and domestic findings or according the public anxieties based on media reports (the most feared hormone 17α - ethinylestradiol). The survey found that at the tap of the consumer , these substances occur very rarely, moreover in trace concentrations. In more than 100 sampled water supplies in three samples of two water pipes only, two of controlled substances were found in a concentration above the limit of quantification (LQ = 0.5 ng / l): three times it was ibuprofen (0.5 to 1.2 ng / l), one of carbamazepine (4.0 ng / l). When sampling in hazardous areas , that means at 23 water treatment plants that draw raw water to the middle or lower reaches of rivers , which are laden by wastewater , in the treated water at the plant outlet at 19 sites they were found one to three substances above the limit of quantification. Most seizures were with ibuprofen (16), followed by carbamazepine (11), naproxen (8) and diclofenac (3); concentration ranged from 0.5 to 20.7 ng / l, with medians below 6 ng / l. In the distribution network , however, they were collected from a values much lower, partly due to mixing with a ground water, probably partly due to chemical oxidation with chlorine.Amount of 17α - ethinylestradiol was in all samples under the limit of quantification (i.e. less than 0.5 ng / l, respectively less than 2 ng / l). For exposure to the detected amounts there is no known health risk because so-called Margins of Exposures comparing minimum daily therapeutic dose and a daily intake from drinking water, are in the order of thousands (7.5 x 10^3) 17α - ethinylestradiol (for exposure used theoretical value at the mid of LQ), respectively. in the order of 10^6 to 10^8 for other controlled substances .Favorable findings relate primarily to the structure of sources of water used for public supply in the Czech Republic, where half the water is produced from groundwater and most of the surface water is taken from protected reservoirs on the upper reaches of rivers. *(Státní zdravotní ústav (odpovědný řešitel za SZÚ: MUDr. Kožíšek). Grantová agentura ČR / číslo projektu: 203/09/1583. Výskyt a zdravotní rizika zbytků humánních léčiv v pitných vodách).* Based on the results of analyzes from 24 countries around the world, these showed that in some areas, particularly in the deltas of major rivers, the small remnants of drugs in water under certain circumstances may occur. Their condition is currently so low, that it becomes practically unmeasurable and can not have a concrete impact to human health . A statement that the water may contain residues of drugs is thus primarily psychological significance, not health. Drug consumption in the EU is constantly rising. Daily are utilized million packs of tenthousands drug kinds. They contain about 300 different active substances. Most often these substances are antibiotics, antidepressants, drugs for diabetes, hormonal contraception dampening pain or inflammation, cytostatics, beta blockers etc. The compounds of these drugs in the human body undergo metabolism. Some of them, however, are from the body still in active status excluded. On the other hand, many people destroys drugs with expired consumption by flushing it to toilet or throwing into the trash. According to the British research ends up in the garbage up to two thirds of expired medicines, into waste water gets up to fifth. Another possible form of water pollution by drugs are seepingfrom poorly secured landfills. To a lesser extent in some locations the pollution may be caused from waste or leaks during the process of pharmaceuticals production. In addition to human pharmaceuticals may be a partial answer to the water pollution as well the drugs applied to farm or domestic animals. In the process of waste water cleaning are substancesin medicines removed only partially, and in some cases hardly at all. In this way pharmaceuticals reach the surface and sometimes underground water, some of which may be a source of drinking water.

The ratio of drug concentrations at the inlet and outlet of the sewage treatment plant enables to identify pharmaceuticals that are removed during the cleaning proces at least. Regarding to the characteristics of these substances can not be assumed that their removal will occur during standard processes for drinking water treatment (aeration, sand filtration, disinfection etc.). More effective is absorption of the substances on activated carbon and ozonation. Even these processes, however, can not remove all of the pharmaceutical substances. To the presence of pharmaceutical residues in raw drinking water, the manufacturer must respond by adding a suitable degree of water treatment technology, if there is no other source of raw water. As an example can be used a water treatment plant in Amsterdam (Holland), where the source of water is located in an estuary of the Amstel river and an effective step in this water treatment plant is the membrane filtration (*Mohou nás ohrozit léčiva v pitné vodě?).* The question of the extent of water pollution by pharmaceuticals was gradually gaining more and more international attention.The project KNAPPE realised in 2008, (Knowledge and Need Assessment on Pharmaceutical Products in Environmental Waters) has mapped the occurrence of pharmaceuticals in the aquatic environment, totally 181 agents in 24 countries. The project was to process 58,600 data details, out of which the average value of a measured environmental concentration (MEC) was determined. The highest rate of pharmaceuticals water pollution was recorded in Germany. Out from all the data contained in the KNAPPE database, the vast majority relates to surface waters. Only 11% refers to the groundwater and 2.2% alone to drinking water. For the method of assessing the extent of the share of pharmaceuticals in drinking water and their potential risk still exist different approaches.

Any assesment method is chosen,while considered a worst-case exposure scenario, for any of evaluated substances was identified health risk in the context of detected concentrations in drinking water. In rare cases, the result can be described as nearly a borderline, but mostly the gap in several orders of concentration was identified, which could be described as human health affecting. However, data based on surveys abroad, can be used in the Czech Republic only partially. The volume and structure of pharmaceutical drugs consumption, the proportion of surface and groundwater use for drinking water production and water treatment used technologies varies from country to country considerably. It is therefore necessary to continue intensively in dealing with this issue in the Czech Republic. So far it is obtained very little data, mostly out of the locations which do not serve as a source for drinking water. In autumn 2009, was realised extraordinary analysis of water in Prague, where in addition to standard and regular checks of drinking water, the samples were also subjected to extensive testing on content of pharmaceuticals.

According to the analysis conducted by an accredited laboratory of state enterprise Vltava River basin - VHL Plzen, in all collected water samples, the compound of medicinal substances was in a such small quantities, that it was impossible even to determine them exactly. Laboratory samples were available from the water treatment plant Želivka of waterworks Káraný and directly from Prague's water supply, as well. (*Mohou nás ohrozit léčiva v pitné vodě?).* One of the kinds of substances that remain in the water after cleaning,are so called “PPCPs” (pharmaceuticals and personal care products)- the active ingredients of drugs. These are artificial, to the nature environment foreign substances (xenobiotics), whose degradation is problematic. They can be found in commonly used detergents, personal care products and of course in medicines. These active ingredients remain active even after they get into the waste water and then into the water cyrcle. There even in small quantities can cause great damage. Other unpredictable effects can arise by their synergistic effects or long-term accumulation in the environment. PPCPs problem is relatively new.

The boom of the pharmaceutical industry in its current form broke out after World War II. Mass drugs and personal care products use is the result of contemporary highly - developed civilizations ,for example we can mention Ibuprofen, the active ingredient in a variety of painkillers. Ibuprofen belongs to one of the most common used substances. Annual consumption in the Czech Republic is about 200 tonnes (plus about 10 tons of pure ibuprofen from illegal drug factories). Ibuprofen provides high stability and it is very difficult to be captured in a wastewater treatment plant. In the past, there were traces of ibuprofen captured in surface and ground waters. Small amounts of ibuprofen was measured recently in the tap water. Currently, however, not the amount that would endanger human health. Another group consists of antibiotics which are decomposed by UV radiation.This method is costly and it is uncertain what effect on other substances contained in the water it would have, therefore in sewage treatment plants it is not commonly used. Antibiotics used

in human and veterinary medicine and in various stages of decomposition penetrate into water and soil. Antibiotics present in the water and sludge deposits in addition reduce the effectiveness of friendly bacteria responsible for decomposition and nutrient cycling. Antidepressants in the Czech Republic in comparison to other countries do not use so often yet.Hormonal contraceptives are a separate group of drugs. They belong to a group of EDC (endocrine disrupting compounds) - substances that can interfere with glandular activity. In this case are meant, substances with estrogenic activity. This means that they imitate the behavior of the hormone estrone. Hormones were the first recorded physiologic substances in waters draining out of sewages. *(Veronica. Ekologický institut).*

Conclusion

This was only a brief overview and an excursion to the issue of drinking water, need to secure the high-quality of drinking water for the population of the Czech Republic , but also the European Union, if we talk about this issue only in a part of Europe. In terms of legislation I mention the basic standard, which is the Act no. 258/2000 Coll. “On the protection of public health and amending and supplementing some related laws”. Implementing legislation for the law On the protection of public health and amending certain related acts can be found in other source. *(Česko. Zákon č. 258/2000 Sb., o ochraně veřejného zdraví).* Under the term water treatment is understood the pollution elimination of the raw water, so as to obtain drinking water, that is sufficiently clean and suitable for human consumption. Regulation of the World Health Organization (WHO) are worldwide generally perceived as the requirements on drinking water quality. In addition to the WHO regulation, each country or region is able to apply their own standards. European countries must abide by the EC Drinking Water Directive. Selection of water treatment methods generally relate to the nature and availability of water resource and the standards set by local authorities. *(Pitná voda. Standardní model - chemická úprava). (Tomek Miroslav, Strohmandl Jan a Jakub Rak. 2014).* Decree no. 252/2004 Coll . in accordance with European Community law establishes hygiene limits for microbiological, biological, physical , chemical and organoleptic indicators of the quality of drinking water, including drinking water, bottled water, hot water supplied by piping, hot water or indoor water pipes, which are structurally interconnected using mixing water pipe with water supply pipe of drinking water and the hot water produced from an individual source for the personal hygiene of staff. The Decree also establishes the scope and frequency of checking compliance of drinking water quality, as well the requirements for methods checking the quality of drinking water. Drinking water must have such physico - chemical properties, that do not pose a threat to public health. Drinking and hot water should not contain micro-organisms, parasites and substances of any kind in the number or concentration that could endanger public health. Indicators of the quality of drinking water and hygienic standards are listed in Annex no. 1 of the Directive. For raw or drinking water, in which the treatment process is artificially reducing the content of calcium or magnesium, the magnesium content may not be after treatment of less than 10 mg / L and a calcium content of less than 30 mg / l. Radiological indicators of drinking water and their limits is determined by special legislation. This legislation regulates the sampling of drinking water and the sampling points. Samples of drinking water, are taken to a control in a manner so that they are representative of a drinking water quality consumed throughout the year and for the entire water supply network, as well. The number of sampling points must at least be equal to the number of shortened analysis according to Annex no. 4, by water supply systems supplying more than 5,000 inhabitants, the number of sampling points must be equal to at least 80% rate of shortened analysis according to the Annex no. 4. The sampling sites should be selected so that more than 50% of the sampling sites were not permanent, but changed each year. Changing sampling points shall be chosen by random selection or any other suitable method that ensures that none of the buildings supplied will be excluded from the possibility of control. Sampling of drinking water is done in places where they should be met water quality requirements (§ 8). In the case of antimony, arsenic, benzene, beryllium, boron, bromates, nitrates, fluorides, chlorides, cyanides, microcystin LR, ozone, pesticidal substances, mercury, selenium and sulfates in which it is not anticipated that their concentration could during distribution between the converter and the point of consumption increase, can be samples of drinking water taken either at the plant outlet

or at appropriate places of water supply network , such as reservoirs, if it demonstrably do not produce changes in the measured values of the indicator. (*Česko. Zákony. Vyhláška č. 252/2000 Sb*.).

Law no. 378/2007 Coll., on Pharmaceuticals, as amended in §88 and §89 provides operators of pharmacies obligation takeover of unusable drugs and drugs of unsatisfactory quality,with expired shelf life, stored or prepared under other than specified conditions, obviously damaged or unused (unusable drugs) must be disposed off, including their packaging, so as not to endanger human life and health or animal health or the environment. When handling unusable drugs shall be treated as the handling of hazardous materials, including lead their evidence under special legislation. Unusable transfusion products and products for advanced therapy, are disposed off as waste, whose collection and disposal is subject to special requirements in order to prevent infection.Disposal of unusable pharmaceuticals are conducted by legal persons or individuals on the basis of consent granted by the regional authority in delegated competence or, in the case of radiopharmaceuticals, by the State Office for Nuclear Safety. About granting consent informs the authority which granted the approval, the Ministry of Health , in the case of human medicine, or the Ministry of Agriculture in the case of veterinary medicine, and communicated information includes the name of the process equipment serving the disposal of unusable drugs, operated by a legal person or an individual.Operators are obliged to hand over unusable pharmaceuticals to the persons referred to §88 paragraph 3. Unusable medicines handed over by individuals to the pharmacy, must be accepted and the pharmacy is obliged to overtake them. The costs arised to a pharmacy to drop off drugs to persons referred to in §88 paragraph 3. and with their removal executed by these persons, is paid by state through the regional office. (*Státní ústav pro kontrolu léčiv. Převzetí nepoužitelných léčiv k likvidaci*). It should be noted that the relevant legislation in this area are for example: Law no. 185/2001 Coll., On waste, the Decree no. 383/2001 Coll., On details of waste management, and law no. 500/2004 Coll., Administrative Procedure Code, and more. Although the situation of water pollution in the Czech Republic through the drug residues is not alarming,it should be noted that this situation may become an important society-wide risk and may result in a significant deterioration of the health status of our population. Contamination of drinking water affects the production of safe food, beverages and quality of the environment on our planet. *(Lukaskova Eva, Pitrova Katerina, Taraba Pavel a Helena Velichova. 2015). (Chlachula Jiri, Sefcik Vladimir a Eva Lukaskova. 2012).*

Abstract

A great deal of attention is being paid to the protection of the population in the Czech Republic both on the part of the executive bodies of emergency management and the government of the Czech Republic as the administrators of these matters. The implementation of all activities is administrated by means of a series of conceptual documents issued by the government that include tasks for individual state administrative bodies in order to secure all necessary activities. One of the fundamental tasks in this field is to solve problems related to supplying the population with drinking water during extraordinary or emergency situations.

Keywords:security, management, crisis, population, plan, water, supply

Introduction

By its Resolution No. 805 of 23 October 2013 the Government of the Czech Republic (CR) approved the "Concept of protection of population by the year 2020 until the year 2030". In the previous period the population protection gradually changed from rigorous planning and implementation of measures laid down by the Geneva Conventions to a broad and comprehensive multi-departmental discipline which became a coherent set of activities and tasks for the responsible authorities that contributed to the protection of life, health, property and the environment in accordance with the current legal regulations of the Czech Republic as well as international humanitarian law. This qualitative step forward was possible due to a close cooperation of professionals from other departments involved (education, health, local development, transport, defense, interior, foreign affairs, agriculture, environment, state material reserves, and nuclear safety) and emergency services of the Integrated Rescue System (IRS). *(Report on the situation of population protection in the Czech Republic, 2015)*
The growing dependency on natural resources leads to greater global competition related to providing access to strategic raw materials and energies. The importance of critical infrastructure protection and means of transport of strategic raw materials in particular increases; these raw materials are characterized by a high degree of vulnerability that could be misused by any state and non-state parties. A trend for abusing the position of an exclusive supplier of these materials or the position of a transit country in order to enforce one's own political and security interests affects the provision of the basic needs of the CR and its allies and what is more, it imperils the political consistency of NATO and the European Union and therefore, it can be classified as an asymmetric threat of a

strategic nature. Also, impacts of climate change on the population's health and environment are very difficult to predict.

However, the actual concerns about this change may lead to an increased tension among countries and what is worse this can result in humanitarian crises with direct impacts on local, national and international structures, including possible escalations of local conflicts accompanied by increased migratory pressures.

A higher frequency of extraordinary events (EE) related to disasters of both natural and anthropogenic origin places growing demands on securing protection of the population, environment and property as well as on increasing the resilience of the whole society and adaptation measures. *(Security Strategy of the Czech Republic, 2015)*

Population protection is a broad "multi-departmental" discipline that cannot be explained and solved only as the fulfillment of tasks of civil protection, in particular warning, evacuation, sheltering and emergency survival of the population (in connection to the Geneva Conventions of 12 August 1949) but it should be understood as a set of activities and tasks of the responsible public administration bodies, artificial and natural persons as well as citizens that in compliance with current legal regulations helps to secure the protection of life, health, property and environment. The tasks of individual bodies are non-transferable and their performance is based on specific provisions of legal regulations. By way of illustration it is possible to mention:

- warning, evacuation, sheltering and emergency survival of the population under the responsibility of the Fire Rescue Service of CR (FRS CR),
- securing public order under the responsibility of Police of the CR,
- protection of life and health of the population under the responsibility of the Ministry of Health and regions,
- management of flood hazards under the responsibility of the Ministry of the Environment, the Ministry of Agriculture and individual flood control bodies,
- ensuring the operation of state and local administration during EE or emergency situations under the responsibility of individual public administration bodies and others.

Emergency management is a necessary extension for solving the increasing impacts of EE, emergency situations and other hazards or interferences in operation of critical infrastructure when it is no longer possible to solve the given situation by means of the standard procedures of public administration bodies, emergency services of IRS or private entities. *(N. Husáková, J. Gurecka, D. Kubala, 2012).* Emergency measures as organizational and technical measures for dealing with emergency situations represent an effective tool for the application of extraordinary procedures, forces and means (for instance by interfering with fundamental human rights and freedoms) and thus help to solve the emergency situation. Since the beginning of 2011 the protection of critical infrastructure has been an integral part of emergency management. *(G. Fedorko, A. Rosová, V. Molnár, 2014).* It is, therefore, a comprehensive system of tools, procedures, rights and obligations, which enables the effective management of the emergency situation. Emergency management represents one of the main pillars that specifically define utilizable measures within the system of population protection. *(Concept of protection of population by the year 2020 until the year 2030, 2014).* One of the essential tasks in the field of population protection which results from the "Concept of protection of the population" is also solving problems connected to emergency drinking water supply to the population. The emergency drinking water supply is highly significant from the perspective of protection of human health and preventing diseases of the population.

Organization of emergency drinking water supply

The organization of emergency drinking water supply to the population during emergency situations is based on the current legal regulations, contractual relationships and demands placed on structural consistency and institutional support. It is prepared and implemented at all levels of public administration starting from municipalities in accordance with the legal regulations of the CR for

dealing with emergency situations and their course. Preparation for managing emergency situations is implemented by means of processing and approval of contingency plans and taking necessary measures arising from them. *(Strohmandl Jan, Tomek Miroslav, Masek Ivan, Safarik Zdenek and Silvie Weinbergerová, 2015).*

When dealing with emergency situations the bodies of the emergency managements proceeds from these contingency plans and based on the particular situation these plans are further specified; subsequently, the bodies provide organizational and coordinating activities in collaboration with the main operators of water supply systems, municipalities, bodies of sanitary services and other selected entities in order to fully cover the given administrative territory. The operators of the water systems, who are also responsible for their standard operation, provide the supply of drinking water to areas affected by emergency situations. In the case of individual water supplies this duty is entrusted to the municipalities (if the affected do not operate their own water main).

The emergency water supply service (EWSS) is the organizational and coordination component of the emergency water supply which upon the origin of the EE and during the states of crisis creates conditions for providing an emergency water supply. In particular, the service lies in the organization and distribution of all necessary water supplies for the population and obtaining information about new sources of drinking water from ground or surface waters. Furthermore, it provides conditions for treatment of raw water into potable water and for provision of repairs and renewal of water facilities and hydraulic structures.

Evidently, the main task of the emergency water supply service is to provide emergency water supply in emergency situations, and namely:

- implementation of security and salvage operations related to water facilities that serve as water suppliers,
- preventive measures to avoid leaking of dangerous substances into groundwater, surface water and soil,
- elimination of possible accidental leakages of dangerous substances into groundwater, surface water and soil,
- searching for new water sources and setting up water collecting systems for emergency water supply,
- provision of a sufficient number of alternative sources of electricity.

To improve the quality of EWSS the artificial and natural persons can also be contractually included into executive entities of the EWSS. In particular, these persons can provide some expert services to ensure the following:

- inspection of water mains and water source protection zones,
- organizational and technical preparations for states of crisis within the framework of the preparation of executive entities of EWSS,
- carrying out emergency repairs or providing technical support during repairs,
- monitoring the situation in the given territory, notifying the appropriate administrative authorities and local authorities as well as informing the population,
- patrols,
- management of water supplies,
- documentation work, evaluation of the EE or emergency situation including calculating expenses incurred, evaluation of the effectiveness of measures taken and suggesting possible changes and additions to them or their cancellation.

The emergency supply of drinking water (alternative supply) may occur during:

- a long-term failure in the electrical power supply,
- accidents caused by weather influences, *(Safarik, Z., Vicar, D., Losek, V., Rak, J. and J. Trojan, 2015).*
- accidents on the main feeder roads of towns and municipalities,
- water sources accidents (an immediate decrease in water yield or contamination by pollutants), *(Safarik Zdenek, Vicar Dusan, Strohmandl Jan, Masek Ivan and Miroslav Musil, 2015).*
- the attack on the sources by an unknown perpetrator.

From the perspective of quality control the most significant hygienic indicators are considered to be odor, taste, the presence of coliform bacteria, enterococci, etc. which are also recommended for daily monitoring. However, on no account is this a closed or fixed set of indicators. The operator and a public health protection body can expand this to set other specific indicators especially if there are suspicions about the presence of dangerous substances or biological agents. *(Lukášková Eva, Pitrová Kateřina, Taraba Pavel and Helena Velichová, 2015).* Similarly, the required frequency of checks should be decided case-by-case (for smaller sources the suggested frequency may not be feasible). *(Cempírek, M., Málek, Z., 2004).*

The quality analyzes of drinking water should be performed:

- daily (for example, for the presence of pathogenic substances, nitrites and for sensory properties of water, etc.),
- weekly (for example for conductivity, chlorides, nitrites and the like), based on the type of pollution with a focus on indicators the values of which were increased during the initial analyze compared to their usual concentration in the given source and as needed *(Rak, J., Vičar, D., Tomek, M., Svobodová, B., 2015).*

In the event of contamination from radioactive substances the competent authority (the State Office for Nuclear Safety) decides on the frequency and extent of inspections. After the available means of supplying drinking water have been exhausted (bottled water, water cisterns, mobile water treatment plants, etc.) and upon request of an emergency response team the ways of water bottling which are not in compliance with current regulations for production of bottled water may be permitted. Nevertheless, it is necessary to comply with the following conditions:

- bottling line: if not used for the bottling table, baby, mineral or soda water, it must be thoroughly rinsed with hot water before using, sanitized and rinsed again with clean water, *(Lukášková, Bilíková, Málek and Šefčík, 2014).*

- water treatment: regular water treatment; for harmlessness it is recommended – where possible – to use a UV lamp, a micro filter (porosity: 0.2 micro pore size) or chemical disinfection by chlorine, ozone or other disinfectant approved for drinking water,
- container: must comply with requirements for contact with drinking water,
- if water is filled into returnable containers their safe and effective sanitization is required prior to bottling,
- labeling of containers: the container must be labeled as “DRINKING WATER – EMERGENCY SUPPLY” and contain the name of the producer, place and date of production and expiration date (determined by a body of sanitary services),
- the method and frequency of inspections of the product will be decided by the body of sanitary services.

Tasks and responsibilities of the municipality during emergency drinking water supply

Organization of the emergency drinking water supply by the municipality plays a significant role; the municipality must secure clean drinking water to be delivered to the right place at the right time and without any deterioration in its quality. The most important factors that affect the emergency supply of the population are as follows:

- nature of the emergency situation,
- number of persons affected by the emergency situation,
- weather conditions,
- hydrological conditions,
- extent of pollution (contamination) of water sources,
- time of pollution (contamination) of water sources,
- duration of contamination of water sources,
- quantity and condition of equipment for drawing, treatment, transportation and storage of water,
- possibilities of transporting water on roads,
- choice of the right way of supplying,
- norms for drinking water consumption,
- possibility to use the assistance provided,
- management work of persons responsible for providing emergency drinking water supply and the like.

Each emergency situation is unique and requires special dealing and therefore it is necessary to consider the fact that every territory can be characterized by various consequences of emergency situations which also significantly affect the process of supplying emergency drinking water to the population. The required amount of drinking water is specified to suppliers of the drinking water by the town or municipality. Among other things, a part of this requirement is:

- specification of the delivery method of drinking water to the population in the first three days of the emergency situation,
- specification of places designated for distribution of drinking water,
- calculating the number and means of transport intended for the supply, their capacity and the capacity of drinking water containers,
- designation of the supplier's representatives who shall be authorized to receive and subsequently distribute drinking water at the distribution point.

In the event of an emergency situation the use of a combination of sources of drinking water supply is expected.

When planning the volume of drinking water for the supply it is necessary to proceed from the minimum amount of drinking water required as an emergency supply of drinking water. In the event of a deteriorated situation when it is not possible to secure specified amounts of drinking water in specified periods and days the municipal authorities can adjust the amount of drinking water according to the situation and the expected development in supplying the population of the municipality.

The total emergency need of drinking water is determined by the sum of the emergency need of water of the population and emergency need of water of all economic mobilization subjects, medical and other facilities serving in the securing the life of the population during the emergency situation.
Emergency drinking water supply during emergency situations is a demanding and complex process of operations that is connected to the planning and taking preventive measures in order to provide sufficient quantity of clean drinking water for the population, economic mobilization subjects, armed forces, security armed forces, health service and other selected entities.
In preparation for the emergency drinking water supply prior to emergency situations it is necessary to suggest and revise different variants of supplying drinking water to the population and other entities in the spirit of principles of logistics *(M. Andrejiová, A. Pavlisková, N. Husáková, 2012, R.*

Németh, V. Molnár, L. Olexa, 2014, G. Fedorko, M. Weiszer, M. Borzecký, 2012). For the actual provision of the emergency supply of drinking water the responsible persons, authorities and organizations must carry out the following tasks:

- to analyze the current state of drinking water supplies,
- to analyze hazards, vulnerability and capacities,
- to draw up feasible documentation which deals with drinking water supplies to the population and to keep the records clearly and flexibly during the course of supplying,
- to take preventive measures to avert hazard or reduce the impact on persons affected by emergency situations,
- to notify the population exposed to hazard in time using all available means,
- to solve any problems arising, to suggest measures and define specific tasks of the responsible authorities, organizations and persons,
- to coordinate activities of all services that participate in solving the tasks set for drinking water supply (objectives, time and place), to deal flexibly with the differences between the planned and the actual state of supplying,
- to secure entities involved in solving problems of supplying.

After a phase of preparation for emergency supply which consists in preparing the analyzes before the occurrence of the emergency situation there is a much more demanding stage of the entire operation of emergency supplying and that is the actual supply after the onset of the emergency situation.

The actual **preparation process for water supply during the emergency situation** consists of the following steps:

- **the analysis of the current state of the drinking water supply,** in which:
  - physical geographic and economical geographic conditions are evaluated and the characteristics of the areas to be supplied with drinking water are evaluated together with the supplying methods,
  - the current situation of the drinking water supply is evaluated based on the data about drinking water consumption of the population, industry, or agriculture and based on the data about the supply systems,
  - the dependence of the drinking water supply on electric energy supplies is assessed, namely from the perspective of production and transportation of drinking water to the consumers,
- **the assessment of security risks and hazards during emergency situations,** in which:
  - potential sources of contamination of the water sources and processing facilities are identified in areas to be supplied with drinking water; these can be agricultural, industrial or other manufacturing facilities which in the event of their destruction during emergency situations may become a source of pollution,
  - environmental conditions of the area to be supplied with water are evaluated in order to analyze the possibility of natural disasters and accidents that could expose the sources of drinking water to hazard *(Mihoková Jakubčeková, J., Benčíková, E., 2014)*,
  - the sensitivity of the used water sources and water processing facilities to the expected security risks and hazards are evaluated,
  - the possibility of taking crucial water sources and facilities out of operation is considered and alternative solutions after their removal from service are suggested,
- **the cooperation of authorities and entities involved in emergency supply:**
  - by creating an overview of technical and other means at the disposal of the given authorities and entities,
  - by close cooperation of entities whose means can be used for emergency supplies, such as adjacent municipalities, companies and other *(Mihoková Jakubčeková, J. 2015)*,
  - by a precise specification of initial cooperation between authorities and entities to avoid delays in managing the emergency situation due to initial confusion and problems which occur immediately after the onset of the emergency situation.

All required information must be processed in the documentation on the emergency drinking water supply which is a part of the contingency plan. The documentation must contain all the necessary information about the area where the emergency supply is expected to be used. Furthermore, it must specify the causes, the number of persons in need of help and it must also contain information about who shall take care of these persons, what means will be used as well as information about mutual cooperation.

Conclusion

Problems of the population protection, especially in the field of the emergency supply of drinking water, are quite extensive and complex. On the one hand, they are regulated by the current laws and regulations of the bodies of the emergency management, and on the other hand they are at the same time dependent on specific measures during the preparation of the actual activity. The actual supply is dependent on many factors the most significant of which is the availability of water sources, drawing and subsequent treatment including the transportation to the affected areas and distribution for the needs of the population (*Rak, J., Juříková, L., Ševčík, D., 2013*). It also depends on the specific knowledge of the situation, sources, means of transport and the actual distribution to the population. This activity is properly planned during the preparation and practice and in the event of the extraordinary or emergency situation it must be fully implemented in order to protect the health and life of the population.

Reliability of models predicting financial distress – Czech models and models from developed economies

Dagmar Čámská, Czech Technical University in Prague, The Masaryk Institute of Advanced Studies, Department of Economic Studies, Prague, Czech Republic, dagmar.camska@cvut.cz

Abstract

This paper is focused on the topic of models predicting financial distress. These approaches are also known as bankruptcy models. The aim of this paper is to compare results for models created in different conditions. On one hand there are national approaches (in our case Czech formulas), on the other hand there are models from developed economies. Formulas from developed economies were created sooner and they are based on financial accounting data of publicly traded enterprises or at least of enterprises operating on the most developed markets. Czech models were created later after replacing centrally planned economy by market economy when the entities had been started to be exposed to the risk of business default. Although there exist critiques against using models predicting financial distress in different time, area and other conditions this research would like to prove that models from developed economies have enough accuracy also for the Czech businesses. The analysis uses methods as Type I Error and Type II Error. The models are verified on the financial accounting of Czech enterprises classified as defaulted as well as non-defaulted.

Keywords: accuracy, bankruptcy models, Czech national approaches, approaches from developed economies.

Introduction

Models predicting financial distress occurred as a serious research task in 1960's in the United States. The beginnings are connected with authors as Altman (1968) and Beaver (1966). These efforts have also spread to other countries. The Czech Republic (formerly Czechoslovakia) was a part of Soviet bloc in that time and therefore these efforts had not started immediately. The reason is that enterprises in Soviet bloc could not bankrupt because of market forces and enterprises performance due to centrally planned economy. The entities could finish only because of the decision of a central authority. After the economic-political shift in 1989 the Czech enterprises have started to be exposed to the risk of business default own or related entities. The need of prediction bankruptcy raised. First step was using foreign approaches and formulas. Second step was creating own formulas for default prediction because the traditional critique of the bankruptcy models states that accuracy is connected only with the models created in the same time, area and with similar data (Grice and Dugan, 2001). The Czech Republic belongs to posttransition economies nowadays which implemented free market economy in 1990's and joined the European Union in 2004. The conditions of the Czech Republic are comparable with conditions of developed economies although Czech capital market is not efficient, there are not many IPOs and Czech accounting standards are used. After the last global economic crisis there has been reopened the debate about the usage of models predicting financial distress. Due to economic changes and further development of the Czech republic it could be possible that prediction formulas from developed economies will provide reliable results for decision making and they will be accurate enough.

Literature overview

There has been created plenty of models predicting financial distress since 1960's. This paper will be based only the Czech national models and then on the approaches which were created in the developed economies but they are also highly discussed in the Czech academic sources. The Czech approaches predicting financial distress are most known by the family indices IN – IN99, IN01

(Neumaierová and Neumaier, 2002) and IN05 (Neumaierová and Neumaier, 2005), followed by Grünwald Bonita Index (Grünwald, 2001) and Balance Analysis System by Rudolf Doucha (Doucha, 1996). New concepts are still coming as or Karas and Režňáková (2013) or Hálek (2013). These two last mentioned cannot be verified because of reasons mentioned by Čámská (2014). The formulas from the developed economies are presented by Altman Z-Score (Altman, 1993), model created by Austrian professor Kralicek (2007) and Bonita index (Wöber and Siebenlist, 2009) from the German speaking area. These foreign approaches are used for example by Klečka and Scholleová (2010) or Čámská (2015) in the Czech economic area. The approaches which will be verified in this paper have already been introduced. The page limitation of the paper does not enable to write full formulas and evaluation tables. The interested readers can find full formulas and evaluation tables in the relevant literature which is quoted in this paper.

Methods

The selected models predicting financial distress will be verified with the elementary methods based on error and reliability rates. The main advantage of tools used for verification is simplicity which enables to present results to auditorium without high mathematical statistical knowledge as in the case of neural networks or rough sets etc. Table 1 displays how the error rates are defined. It works with two kinds of error – Type I Error and Type II Error.

Table 1: Type I Error and Type II Error, Source: author based on Fernandes (2005)

		Estimated	
		Non-Default	**Default**
Observed	**Non-default**	True	False Alarm (Type II Error)
	Default	Miss (Type I Error)	True

Type I Error shows how many defaulted entities are classified as a non-defaulted entity by the specific bankruptcy model. Type II Error is a mistake in the case of classification of non-defaulted entity. It means that non-defaulted entity is classified as a defaulted entity by the used bankruptcy model. The total error rate would be a figure of sum of Type I Error and Type II Error divided by a number of all analyzed enterprises. The total error rate is not an appropriate measure when the analyzed groups are not balanced. It means that the number of defaulted enterprises should be equal or almost equal to the number of non-defaulted enterprises.

Data Samples

There will be used two data samples for the models' verification. One sample contains enterprises coded as non-defaulted because they created positive Economic Value Added (EVA) for three consecutive years. The positive EVA can be indicator of good enterprise performance (approved by Synek and Kislingerová, 2010 and Veber and Srpová, 2005) This sample consists of more than 650 enterprises. The second sample contains enterprises coded as defaulted because their insolvency proposals have been declared. This sample consists of almost 100 enterprises. Both samples contain financial accounting data of Czech enterprises belonging to construction and manufacturing industry. The limitation is that many enterprises do not publish their accounting data (Čámská, 2013 or Czech Credit Bureau, 2013) although it is an obligation.

This section should follow keywords. This section should provide background of the study and highlight research motivation.

Results

The enterprises from the data samples are classified by the selected models predicting financial distress. After the models are evaluated because their classification is compared with the real state of enterprise – defaulted and non-defaulted. The results are displayed in tables 2-5. Tables 2 and 3 show results of models using three evaluation zones ad healthy, grey zone and unhealthy. Tables 4 and 5 introduce results for models using more evaluation zone. It is Bonita Index and Grünwald approach.

Table 2 contains evaluation of the selected models predicting financial distress on the defaulted entities. There are absolute figures in the columns unhealthy, healthy, grey zone and unevaluated and as well as there are relative figures which are more important because they enable better comparison. Type I Error is a ratio which shows the number of incorrectly classified defaulted entities divided by all defaulted entities from the data sample. The highest error ratio is connected with Balance Analysis System by Rudolf Doucha. This approach has also very low reliable ratio (the number of correctly classified defaulted entities / the number of all defaulted entities). The low reliable ratio is caused by three reason – high error ratio, high number of entities classified in the grey zone and unfortunately high number of entities unevaluated. The models sometimes are not able to compute results for specific accounting data because some items are equal to zero and authors have not let any recommendation how to modify their approaches in this case. IN05 and Kralicek have the highest reliability ratio but it does not mean automatically that these approaches are the best. It is necessary to compute results also for other kind of entities – non-defaulted. The well performed models can be very strict and they can punish non-defaulted entities.

Table 2: Evaluation of national and approaches from developed economies on defaulted entities, Source: author's own computation based on financial accounting data

Model	Unhealthy	Healthy	Grey Zone	Unevaluated	Reliability	Type I Error
Altman	71	5	21	1	0.72	0.05
IN99	71	6	20	1	0.72	0.06
IN01	77	3	17	1	0.79	0.03
IN05	83	5	9	1	0.85	0.05
Doucha	51	19	12	16	0.52	0.19
Kralicek	82	4	8	4	0.84	0.04

Results for non- defaulted entities are displayed in Table 3. Balance Analysis System by Rudolf Doucha has repeatedly the highest error rate. Kralick has the highest reliability rate and it is followed by Altman and IN05. The older versions of IN indices IN99 and IN01 are too strict and they punish even entities creating the possitive Economic Value Added. If we compare Altman and Kralicek it seems that Altman provides better results for a decision making process because its error rate is significantly lower compared with Kralicek. Sum it up Altman, IN05 and Kralicek provided enough accuracy in the case of the verification on non-defaulted entities.

Table 3: Evaluation of national and approaches from developed economies on non-defaulted entities, Source: author's own computation based on financial accounting data

Model	Unhealthy	Healthy	Grey Zone	Unevaluated	Reliability	Type II Error
Altman	12	438	209	1	0.66	0.02
IN99	17	157	485	1	0.24	0.03
IN01	6	364	289	1	0.55	0.01
IN05	18	424	217	1	0.64	0.03
Doucha	89	297	262	12	0.45	0.13
Kralicek	44	455	159	2	0.69	0.07

Table 4 is dedicated to Grünwald approach whose results have to be displayed separately. It is caused by the reason that this model originally uses four evaluating zones – very unhealthy, unhealthy, good health and very good health. There is no middle zone between unhealthy and healthy. For computing error rates and reliability rates in the case of both data samples the evaluation zone very unhealthy and very good health were used. The error ratios for both groups are low. Unfortunately the reliability ratios are lower because of non-evaluation of many entities. The share of unevaluated entities is very high in the case of both data samples and therefore the use of this Czech approach is limited.

Table 4: Evaluation of Grünwald approach, Source: author's own computation based on financial accounting data

	Defaulted entities	Non-defaulted entities
Very unhealthy	48	11
Unhealthy	2	1
Good health	2	33
Very good health	9	423
Unevaluated	37	192
Reliability	0.49	0.64
Error	0.09	0.02

Table 5 is dedicated to Bonita Index whose results have to be displayed separately. It is caused by the reason that this model originally uses eight evaluating zones – extremely good, very good, good, mild good, bad, mild bad, very bad, extremely bad. The valuating zones are ordered from the healthiest one to the most unhealthy one. For computing the reliability rate in the case of the defaulted sample the evaluation zones extremely bad and very bad were used very unhealthy and very good health were used. For computing the error rate in the case of the defaulted sample the evaluation zones extremely good and very good very used. For the non-defaulted sample it was used oppositely. Both error rates are very low. It means that this index does not classify entities incorrectly. Middle zones are used but not extremely because the reliability rates especially in the case of non-defaulted entities are high. The share of unevaluated companies is almost not detectable.

Table 5: Evaluation of Bonita Index, Source: author's own computation based on financial accounting data

	Defaulted entities	Non-defaulted entities
Extremely good	4	262
Very good	2	99
Good	2	125
Mild good	0	87
Bad	17	86
Mild bad	2	0
Very bad	12	0
Extremely bad	57	0
Unevaluated	2	1
Reliability	0,72	0,91
Error	0,08	0

Conclusion

This paper was focused on the verification of the selected models predicting financial distress. The verified models were Czech national approaches as well as approaches designed in the developed economies. The verification was done on the financial accounting data of almost 800 Czech enterprises. At the end it is possible to answer a question which models should be recommended for the further use. The recommended approaches are Altman, IN05, Kralicek and Bonita Index. These models predicting financial distress have very low error ratio in both data samples and as well as high reliability ratio in both data samples. The other tested approaches did not have enough accuracy for decision making or they are based on obstacles that they do not evaluate many entities because their accounting items are equal to zero. Some errors occurred but it is no exception for researches verifying models' accuracy and even not for models' construction. Some level of errors is natural. The models predicting financial distress are not a physical law, they just work on probabilistic roots.

A Framework for the Annotation of Arabic Legal Documents

Imen Bouaziz Mezghanni, MIRACL Laboratory, Sfax University, Sfax, Tunisia, imen_bouaziz_miracl@yahoo.com
Faiez Gargouri, MIRACL Laboratory, Sfax University, Sfax, Tunisia, faiez.gargouri@isimsf.rnu.tn

Abstract

Improving retrieval systems performance involves discovering more relevant answers and at the same time reducing the number of non-relevant ones that will be retrieved. Providing advanced query functionalities can serve as support to the improvement. In the legal domain, known by its complexity, advanced querying requires on beyond a rich annotation of documents that takes into account their semantic content as well as their structure. The proposed approach demonstrates that the use of NLP techniques and tools in conjunction with a domain ontology that automate the process of information extraction from legal texts through a meaningful annotation is of paramount importance to provide a better access to Arabic legal information.

Keywords: Legal documents annotation, Document's structure, Document's semantic content, domain ontology.

Introduction

Usually non-professional readers analyze a sentence related to a specific subject alone without considering other ones having the same topic. Yet, another sentence may disrupt the idea extracted from the former and so on, which can lead to the so-called radicalism. The best idea to overcome this problem is to always consider the text as a block. This means that gathering all sentences having the same topic, produce certainly a coherent, reasonable and non-radical sentence offering a global vision.

In a highly specialized and professional field such as Law, textual resources are highly delicate. Lexical, syntactic and semantic features characterizing these texts are the origin of this delicacy. Thus, a simple misunderstanding may induce to bad analyses. The idea already mentioned can be applied to legal texts and this is justified by the fact that its subjects are not linear (separate themes). The legal text is rather a single network composed of related and overlapped topics, covering a trellis that one should always take it as a block.

Having an efficient retrieval system, in the legal field, able to return all pertinent documents of a specific type that focus on a given topic defining a particular legislation, as well as their relative jurisprudence can even open new perspectives of interpretation and therefore of argumentation.

Getting from a corpus of textual information an annotated output is a demanding task, generically referred to as the knowledge acquisition bottleneck. A potential solution to this problem Information Extraction from text (IE) considered as a promising technique to improve the performance of information retrieval systems. This ability has been identified in many legal areas as in ontology construction by Lame (2004) and Peters (2009), text summarization by Moens et al (2009), Hachey and Grover (2006), extraction of precedent links by Jackson et al (2003) and factor analysis by Ashley and Brninghaus (2009) equally by Wyner and Peters (2010).

Since the annotation of unstructured linguistic information presents a challenge in legal information processing, we aim in this article to provide an approach to produce annotated Arabic legal texts from which information can be extracted, by using domain ontology and a linguistic tool. The paper is organized as follow. Section 2 reviews some recent Arabic related works. Section 3 and 4 present

characteristics of legal documents in terms of structure and content respectively. The approach, which combines the use of a domain ontology and linguistic tool, is described in Section 5. Section 6 presents results analysis. We conclude our research work and give some ideas for further works in last section.

Annotated Arabic Documents

Arabic language has received less attention compared to other languages especially in the field of annotation.

Laymen and Al-khalifa (2009) have established AraTation tool, one of the earliest tools for semantically annotating Arabic News content on the Web documents. The tool is capable of extracting named entities using an Arabic location ontology designed specifically for this purpose. Although AraTation uses an ontology for the annotation process, the ontology only covers location names and is not useful for lexical semantic relations.

Zaidi et al (2010) have presented a different work on Arabic language annotation based on GATE NLP toolkit elaborated by Cunningham and Peters (2010). The presented system was dedicated to annotate Quranic Corpus through predefined patterns that use tokenized and morphology analyzed corpus with Part Of Speech (POS) features for extracting also named entities. It's a good approach for extraction collocation, but the authors presented few forms of extraction only Noun-Adjective annotation with low result.

The majority of tools is based on Arabic named entities recognition and they are not available for download and testing. As a result of this brief literature review, we concluded that there are limited resources publicly available to semantically annotate Arabic sources, which motivates us to perform our research work.

Structures of Legal Documents

Legal documents are explicitly structured in three dimensions:

- **The document architecture dimension:** It defines the overall logical organization of information contained in the document called "logical structure" of the document. It describes the relationships that may exist between its component parts (books, chapters, sections, paragraphs, etc). A legal code is, for example, composed by a title, and books, themselves composed of a title and chapters and so on down to the basic elements. An extract from its tree representation may be in the form presented in Figure1.

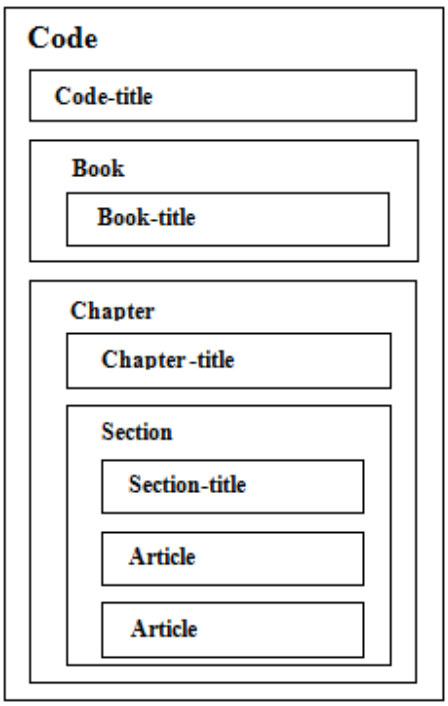

Fig 1. An example of a code's levels

- **The Meta-data information:** Meta-data are particular information that aren't in the original content of the document. Metadata are added to improve comprehension and classification of the document.
- **The Reference dimension:** It defines the relationships with other documents. These references can be to legislation, court decisions, modification, repeal, codification, etc.

Vocabulary of Legal Documents

Legal language is a language of specialty that, compared to the common language, has the obvious linguistic specifications reflecting the ambiguity and inaccuracy of the legal vocabulary. On the other hand, Arabic is a Semitic language that suffers from important morphological and orthographic characteristics that make the extraction of knowledge more complicated.
Arabic legal language combines thus several challenges in different levels.

- **Lexical level**

Legal language suffers from a high lexical heterogeneity coming from derivation, composed terms (like: Noun+Noun, Noun+Adjective, Noun+Adjective+Adjective, etc.) and sometimes caused by borrowed words from other languages.

- **Morpho-Syntactic level**

An important number of aspects are noted at this level. Words are written from right to left; Word formation: The presence of agglutinated forms (forms with proclitics and enclitic) causing several lexical ambiguities. Figure 2 illustrates what can be agglutinated to terms. They are given in Arabic along with their English translation and their transliteration using Xerox Morphology System[i].

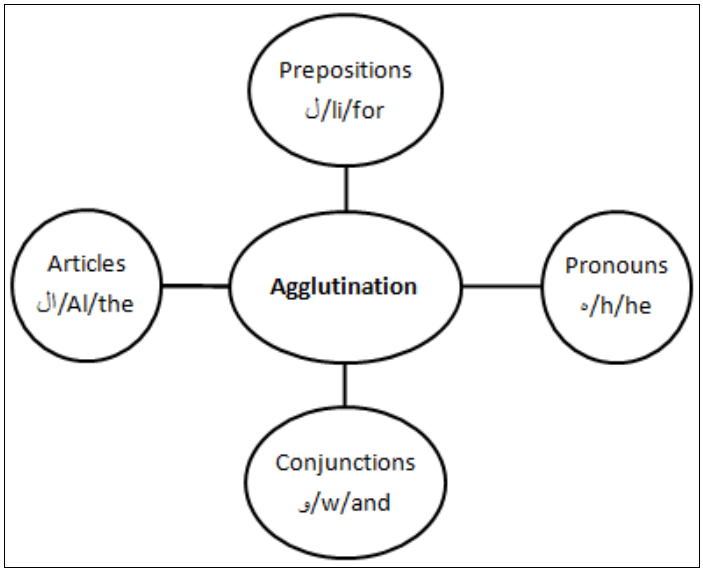

Fig 2. Agglutination's forms

Furthermore, words are complex and the meaning of some words is not composed of the meaning of their parts, the context in this case is very important; Arabic is a morphologically language providing flexibility in word formation. Besides this, sentences are long and complex which complicate the syntactic patterns; other issues consist of the absence of diacrities (voweling) leading to a high ambiguity in word analyzing and of the use of the undefined. This case concerns the Arabic words denoting a non-specific thing. Among the signs indicating that the word is undefined is the presence of "tanwine", however most of texts are not vowelized, and suffer from the absence of the article before the word; Uncompleted passive structures (characterized by the absence of the agent or complement of the subject of the sentence, which is implied); Negation and restriction marks having conditional value; Demonstrative marks and Modal marks characterize likewise Arabic legal texts.

- Stylistic level

Three different styles represent the legal documentation: Legislative style; Judicial style and Doctrinal style.

- Pragmatic level

- The implicit reference to the issuer of the legislative statement;
- The implicit reference to a possible situation, etc.

Proposed Approach

Document's structure constitutes a valuable source of information that would be important to take into account in the information extraction process. In fact, distinguishing clearly between the document's hierarchical outline structure and relations between them (especially generalization and specialization) helps to locate quasi-automatically key terms in the document, through automatic natural language processing (NLP) tools. Moreover, the structure of documents in the collection and the cross-document relations reveal additional relevant data concerning the meaning of document's elements. Metadata aims too at facilitating in the discovery of relevant information, more often classified as resource discovery.

Most methods for documents processing exploits the natural language they contain and ignore information from its structure. On the other hand, few approaches use the structural elements of documents to generate automatically or semi-automatically models or patterns based on structure. We cite the example of Kamel and Aussenac-Gilles (2009) which uses the document's structure in the process of

ontology's construction. Their approach is based on two stages. A first stage is based on the definition of structural patterns to take into account the hierarchical structure such as headings, lists and enumerations for providing a first core ontology. The second phase is to enrich this core by analyzing the text by natural language processing tools for the definition of lexical-syntactic patterns to take into account lexical, syntactic and semantic elements of plain text.

Amardeilh et al (2005) represents the structure of a document as a conceptual tree in which each node is mapped to a concept from the ontology via rules defined manually whereas Aurlien (2009) shows the interest of structural and linguistic analysis of the documents for summarization.

To the best of our knowledge, there is no previous works that deal with the processing and annotation of Arabic legal documents which make the task a real challenge. The approach, shown in Figure 3, based on the simultaneous use of domain ontology as well as a linguistic tool. It has five main steps.

1) Corpus Selection and Preparation.
2) Identification of documents Types by the use of "Arabic Legal Document Ontology (ALDO)", an ontology that we have created manually composed of the distinct types of documents.
3) Derivation of corresponding structural grammars.
4) Application of morphological then syntactic grammars by the use of NooJ tool.
5) Projection of grammars on documents for obtaining tagged files by XML Format.

Corpus Selection and Preparation

Given the obvious lack of Arabic resources and the unavailability of the existent free corpora, we built our own corpus "PenalAr". Our intention is to share it in the future with other researches either for making a comparative study with us or absolutely for other applications.

The used documents are collected from the Tunisian official publication Journal which gathers laws, decrees, and decisions from various administrations. PenalAr consists of the Criminal Procedures Penal Code (46 articles are used) and 20 Criminal Law Decisions of the Cassation Court is composed of 16737 tokens as presented in Table1. These documents are available on an internet site "http://e-justice.tn" which intends to be a web portal of Justice and Human Rights. The work on this code is justified by the fact that codes are good points of entry for conceptualization of the legal field. In its first version, the corpus was submitted to be subjected to a treatment sufficient to ensure its cleaning from orthographic errors and normalization. As a result to the following steps, the corpus will be automatically annotated with syntactic grammars elaborated through the linguistic platform NooJ constituting the final version.

Table 1: Corpus description

Document	Tokens
Code	2737
Decisions	14000

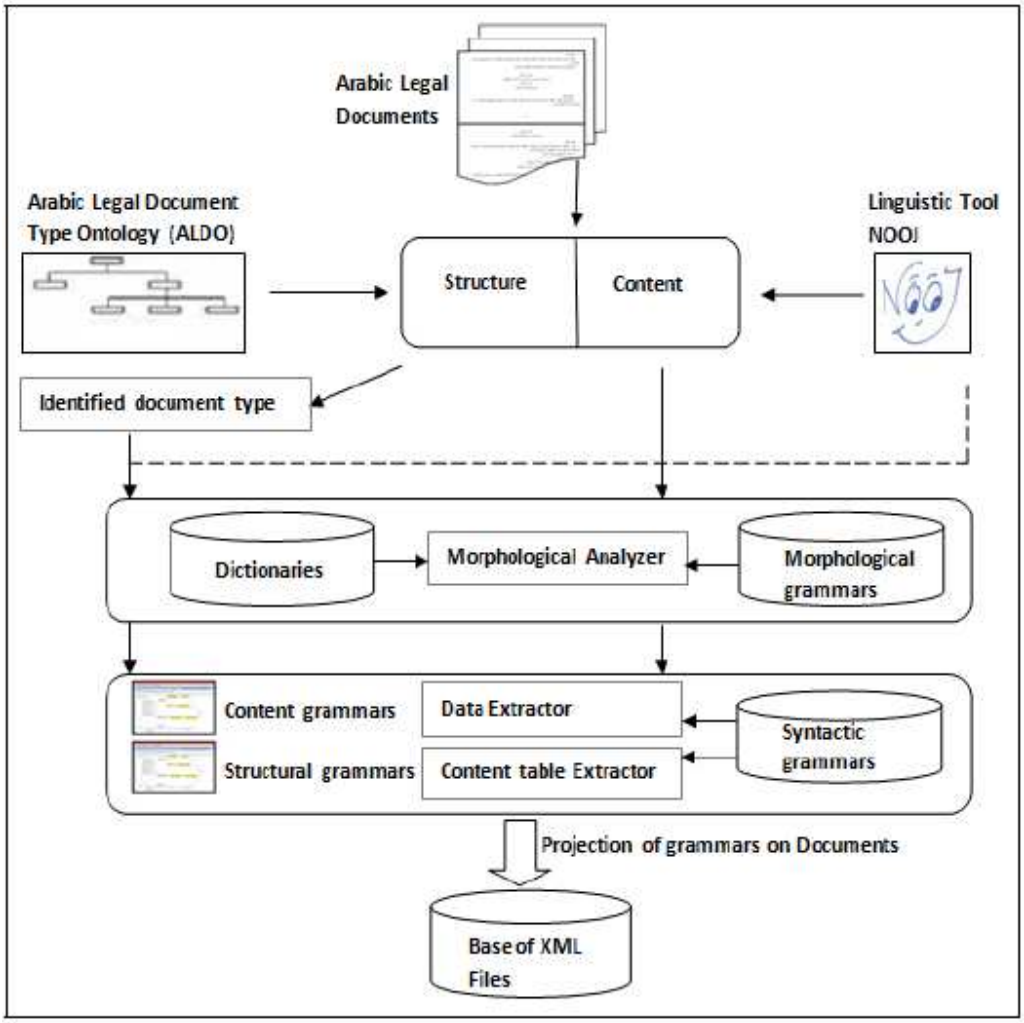

Fig 3. Approach Architecture

Identification of documents Types

Legal documents have different types, distinct structures (hierarchical structure, collection structure) and meta-data. These specific structures can be grouped by families or more precisely by document types called generic logical structures, that's why we have developed an Arabic Legal Document ontology (ALDO) defining a general legal document class, specifying all types of elements that can be used in the logical structure of a document of this class. Relations between these sub-classes are modeled while their content is not modeled here, in order to make the ontology very flexible and interoperable thus make each component directly accessible and reusable.

On the other side, legal documents are interrelated and cannot be considered in isolation. They usually contain a lot of references to other texts. References to other texts which is called "Intertextuality" is so relevant in the context of legislation and jurisprudence so it is greatly important to follow the cross references in the underlying legal documents and consider the additional information in the cited documents that contribute to the interpretation of the source texts. The document relations taken into

account in the ontology are categorized into three different types: Jurisprudence / Jurisprudence: J-J, Jurisprudence / Legislation: J-T and Legislation / Legislation: T-T.

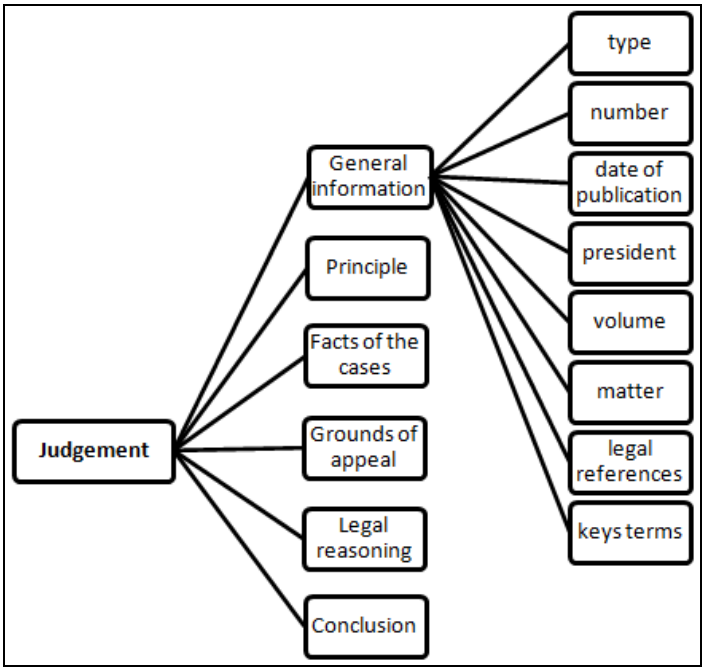

Fig 4. The judgment's structure

Figure 4 shows the judgment class from (ALDO) defining the structure of a document of judgment. We underline the existing structural models that are visually prominent of the judgment such as general information; including the judgment's number, type (criminal, civil, administrative), date of publication, the volume in which it was published, the matter, the cited legal references and some keywords; principle, facts of the cases, grounds of appeal, legal reasoning and at the end a conclusion.

Identification process is simply carried out by comparing the document title with the ontology. The title is often comprised by the first words in the document. In the legal documents, they are sometimes preceded by the republic and ministry names.

Derivation of corresponding structural grammars

Once the document type is identified, the corresponding path in the ontology will be translated by a syntactic grammar that will be applied to the document for extracting its "table of contents".

In fact, key terms are generally introduced in the document's header (title, table of contents: the introduction, the chapters and sections titles, enumeration lists, the conclusion and the reference list). Both document's authors and readers usually focus their attention on these parts. In order to recognize them, we have elaborate grammars represented as directed graphs and apply them to documents.

The graph in the Figure 5 detects the hierarchic structural information of a legal code by recognizing its table of contents. Noting that each code is thematically divided into chapters, sections and subsections and its basic elements are articles which can contain various kinds of enumeration lists. Enumerative structures benefit from an easily identifiable layout, maintain relations between their different items, present regularities and occur frequently. The result is then a list composed of titles for rapid information on the main topics of the document.

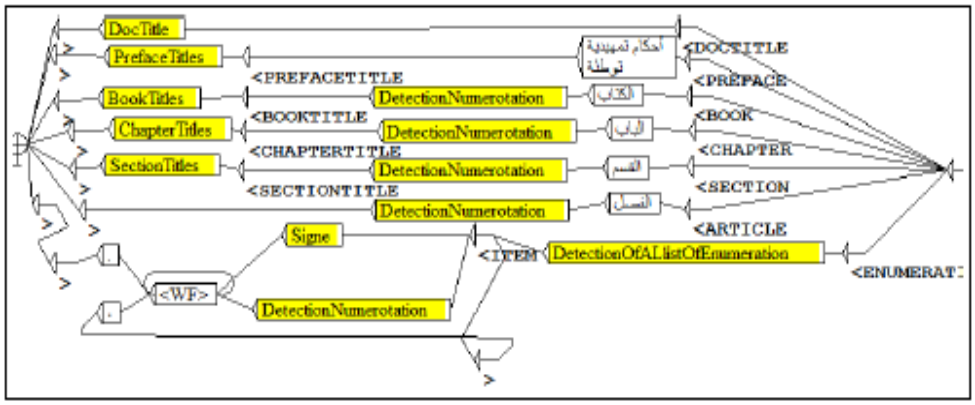

Fig 5. Grammar of legal code structure detection

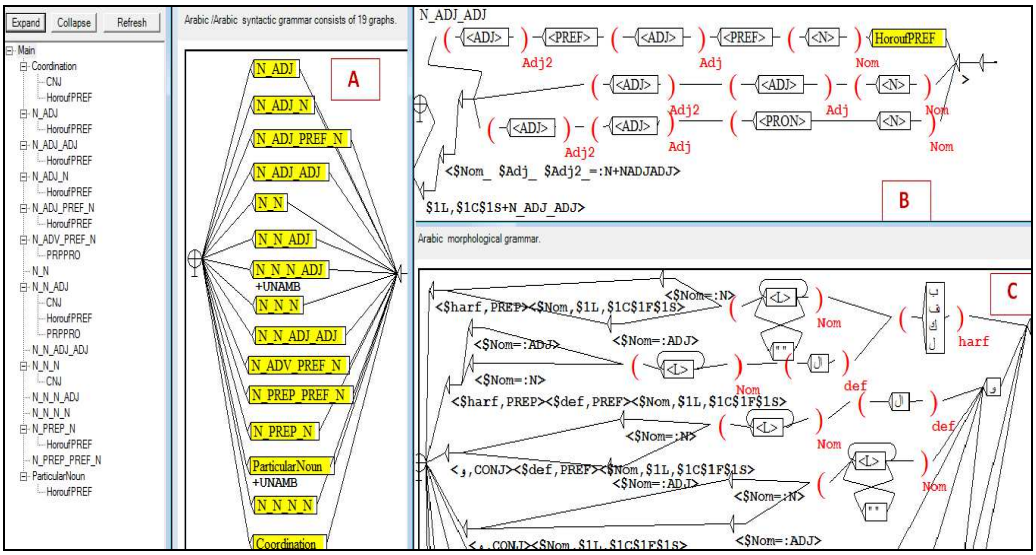

Fig 6. A,B. Graph of Syntactic grammar, C. Graph of morphological grammar

Application of morphological and syntactic grammars

Legal written sources are currently almost exclusively composed of natural language texts (unstructured information) so information extraction from texts requires especially NLP.

NooJ built by Silberztein (1993) is used as a software tool to recognize linguistic elements. It is a freeware, linguistic engineering development environment used to formalize various types of textual phenomena (orthography, lexical and productive morphology, local, structural and transformational syntax) using a large gamut of computational devices. It includes tools to construct, test, debug, maintain and accumulate large sets linguistic resources, and can apply them to large texts.

This step is consisting of three fundamental tasks:

- Construction of morphological grammar

Agglutinative forms are not present in the NooJ's dictionary of inflected forms. To solve this issue, a morphological grammar of agglutination is constructed. A part of this grammar is shown in Figure 6.C.

- Creation of an Arabic dictionary for legal compound terms

NooJ can treat simple and compound word using a set of dictionaries in different language except the Arabic concerning the compound terms. For this reason, it is crucial to create a dictionary of legal compound terms so as to recognize them later.

Compound terms are extracted manually. Noting that Arabic NooJ's dictionary generally associates each lexical entry with an inflectional and/or derivational paradigm to describe its syntactic and semantic and inflectional (gender, number, conjugation...), and derivational features. For instance, each Noun in the dictionary entry has the form presented in the following form: "محكمة, N+tribunal+FLX=Flexion2+DRV=Manazil30:Flexion16". This line means that the entry محكمة/mHkmp/court has the category Noun (N), described in French as 'tribunal' and that is conjugated by applying the grammar 'Flexion2' and its derivation follows the grammar 'Manazil30:Flexion16'. In the same way, manually compound terms are added to the dictionary.

In the same way, manually compound terms are added to the dictionary (legal dictionary) with its semantic attribute referring to the category of the compound noun in order to treat each category separately in the syntactical grammar. For facilitating this step, we designed a java prototype allowing the insertion of new terms in a semi-automatic way. The insertion process is based on the determination of the category of the new term and its classification among existing input. We apply the nearest neighbor algorithm to return the class of the term. A new type will be added to the dictionary if this latter is not determined. The designation of the term is extracted from some terminologies uploaded and stored in the same project. By this way, our framework can be extended to endure various matters of the law and even to other domains.

- Construction of syntactical grammar

In order to treat each category separately in the syntactical grammar, we have added semantic attribute referring to the category of the compound noun. Also we have studied to each entry their possible different derivational, inflectional forms as it is illustrated in Figure 7. To allow this process, Inflectional and Syntactical grammars are constructed. The former, based on generic commands as shown in Figure 7, concerns the Inflectional/Derivational description in order to generate the different voweled forms of the dictionary entries. For us, this grammar is obviously costly in terms of time since the legal text is usually very rich by variants. The latter is dedicated to extract all related derived and agglutinated forms.
As it is illustrated in the Figure 6.A, the root graph called the grammar is composed of sub-graphs where each one contains the appropriate treatments of the specific grammatical category like for the category N_ADJ_ADJ in Figure 6.B.

```
# Generic Commands:
# <B>: keyboard Backspace
# <C>: change Case
# <D>: Duplicate current char
# <E>: Empty string
# <L>: keyboard Left arrow
# <N>: go to end of Next word form
# <P>: go to end of Previous word form
# <R>: keyboard Right arrow
# <S>: delete/Suppress current char
# Arguments for commands <B>, <L>, <N>, <P>, <R>, <S>:
# xx number: repeat xx times
# W: whole word

```

Fig 7. Flexion grammar

Projection of grammars on Documents

The projection of constructed grammars on documents with NOOJ is articulated around three steps:

- Selection of the used dictionaries in the "Lexical Analysis" in Preferences from Info Panel
- Selection of the appropriate Grammars in the "Syntactic Analysis" in Preferences from Info Panel
- Performing the Linguistic Analysis in TEXT Panel

After having applied the grammar to the document, NooJ can extract the matching sequences and builds a concordance. It is also possible to ask NooJ to produce an annotated text by applying the grammar to the text. The resulting text can be exported as an XML document, in which XML tags have been inserted.

Evaluation

The data used in the experiments consists of the new-tunisian-constitution's draft released on June 2013 after Tunisia's 'Jasmine Revolution' and 20 decisions 20 Criminal Law Decisions of the cassation Court containing 9870 tokens. The constitution is composed of 164 articles. It is published on the Tunisia OpenGov site[ii]. We use a sample of 50 articles for the test including 1342 tokens. The decisions are available on the web portal site of Justice and Human Rights "http:// ejustice.tn".

The example given in Figure 8 presents a structural annotation of the Tunisian-constitution document and the sample given in Figure 9 shows a portion of an article before and after the whole annotation.

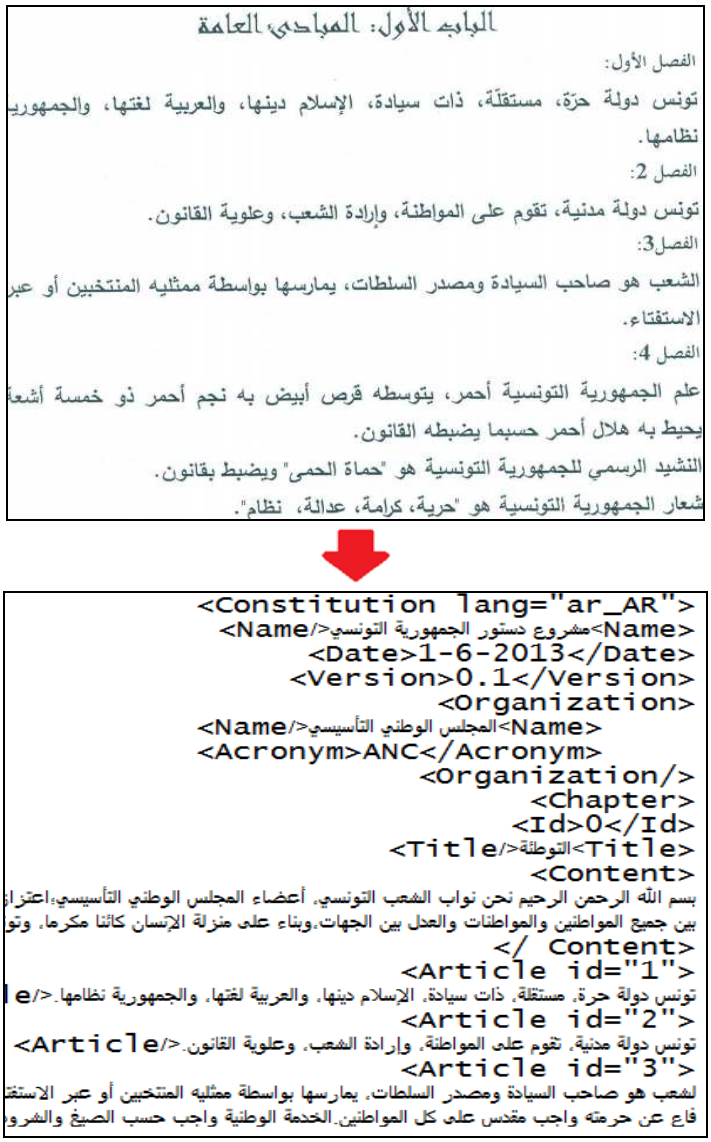

Fig 8. An excerpt of Tunisian-constitution and its corresponding structural annotation

At this point, it is necessary to mention that the results presented are the consequence of the recognition of the expressions expressed by grammars (structural and syntactic). Each annotated term (simple ST or compound CT) is defined by its lemma and semantic attributes referring to its description as well as its grammatical category.

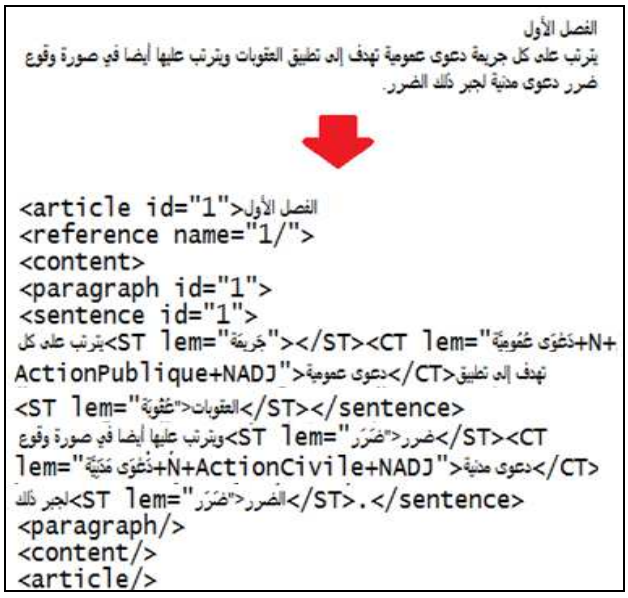

Fig 9. An example of the result annotation

We depend on two important measures which are commonly used to evaluate such process: precision and recall.

- **Recall:** is defined as the returned number of relevant annotations divided by the total number of existing relevant annotations.
- **Precision:** is defined as the returned number of relevant annotations divided by the total number of annotations.

Table 1: Result of evaluation

Measures/Annotation type	Syntactical	Structural
Precision	85%	73.7%
Recall	94.43%	100%

From our experimentation, we can say that our approach achieved best results as shown in Table 1 which confirm its performance since as regards testing and results on this data, satisfactory ratio are reported for syntactic annotation as well as for structural annotation.
The incorrect matches correspond mostly to the syntactic annotation due to sequences containing anaphora.

The provided results by the approach have been assessed and validated by two legal experts, a lawyer and a Professor of Law. The former assessed the structural annotation while the latter evaluated the second kind of annotation: the syntactic annotation. Their relevance judgments have achieved an acceptable level of agreement since the proposed approach offers a potentially useful alternative to the manual assignment of index terms. For comparisons with other methods, since no previous work in Arabic domain using NooJ in the process of documents annotation and retrieval and other methods found. So we cannot compare our methodology with other researches.

The aim of the evaluation is to assess the framework's performance, for that we implement a prototype of a search process. Indexing is used for the quick retrieval of relevant documents for a search query. The corpus of all annotated documents is stored in a database to begin the process of indexing and searching. We depend on LUCENE search engine in this process which is free open source information retrieval library released under the Apache Software License. LUCENE was originally written in Java, but it has ported to other programming languages as well.

After the identification step, the user can begin writing his query which will be the annotation type coming from the process of documents annotation and then send the query. The search process starts over the annotated documents and the results will be presented in the form of documents that match the query as shown in Figure 10 A and B.

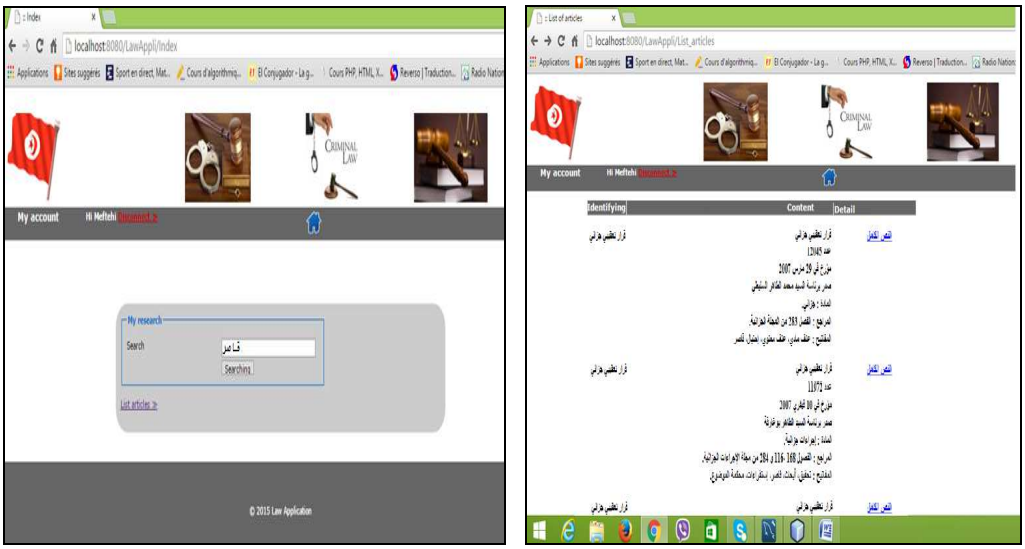

Fig 10**. A,B. Search using the word "قاصر/minor" and its result**

Conclusion

The present paper has given an overview of how the Semantic Web technology, notably the ontologies, and Natural Language Processing (NLP) apply to Arabic legal textual information to support annotation for effective retrieval. In our view, it holds great promise in making legal information more transparent and available to more legal professionals. The use of NLP in conjunction with ontologies to annotate legal texts is a fast-developing, results-oriented area which targets meaningful applications for legal professionals. The annotation will be more fruitful by resolving textual grammatical cohesion. We will be charged of this deficiency as perspective.

Analysis of Key Factors of High Level Monthly Earnings in the Czech Republic

Elena Kuchina, University of Economics, Prague, Econometrics de., W Churchill Sq. 1938/4, Czech Republic, xkuce10@vse.cz

Abstract

This paper focused on the analyzing the key drivers of differentiating the high level salaries from the middle and low ones in the Czech Republic. Two segments were examined separately: employees at the managing position and employees who are not at the managing position. The main data source was the Survey of Adult Skills (PIAAC). Importance of the different predictors in the differentiating the high level salaries from the others was examined by Stochastic Gradient Boosting approach. The evaluation of the final model was conducted based on the AUC value using the testing set: for employees who are at managing position the AUC is equal to 0,7304; for the segment of employees who are not at the managing position the AUC is 0,8176. For both segments the level of education, gender, regionality, area of study, learning activities, index of readiness to learn and index of using ICT skills at home play a significant role in the differentiating between the high monthly earnings and middle or low earnings.

Keywords: stochastic gradient boosting, over-fitting, tuning parameters, AUC, ROC

JEL Classification: C52, C53

Introduction

There are many factors which can have an impact on the monthly earnings. It can be the level of education, the area of study, work experience, different kinds of learning activities, personal and professional skills, some demographical features and many other factors. The key factors determining the person's monthly earnings may differ for different groups.

The current paper examines the key drivers of differentiating the high level salaries from the middle and low ones in the Czech Republic. Due to the fact that for the employees at the managing position and for employees who are not these factors can be different, the analysis of the earnings' dependence on the different factors was conducted separately for employees who are at the managing position and for employees who are not. Importance of the different predictors in the differentiating the high level salaries from the others was examined by Stochastic Gradient Boosting technique.

The paper is structured into three parts. Firstly, the data set used in this research is described. Secondly, the methodology, determining the continuity of the steps in the empirical part, is introduced. The final chapter is focused on the empirical analyzing and modeling. The paper is finalized by the main conclusions.

Data Set

This section discusses the input data used in the analysis. The main data source was the Survey of Adult Skills (PIAAC[1]) which took place from August 2011 to March 2012 in 24 countries. For the purpose of the current research the Czech Republic data set was examined.

The remuneration of the employees and self-employed people is described by monthly earnings including bonuses for wage and salary earners and self-employed, PPP corrected measured in US $. The respondents with monthly earnings more than 10 000 USD were excluded from the analysis. The explanatory variable (y) takes the value 1 when the monthly earnings are equal or exceed 2000 USD,

[1] http://www.oecd.org/site/piaac/publicdataandanalysis.htm

otherwise the value is equal to 0. The explanatory variables, which impact on the monthly earnings' level is examined, are the following:

- AGE_C - respondent's age (9 categories: aged 19 and younger, aged 20-24, aged 25-29, aged 30-34, aged 35-39, aged 40-44, aged 45-49, aged 50-54, aged 55 or older)
- GENDER_R - respondent's gender (2 categories: male, female)
- EDLEVEL3 - educational level of the respondent (3 categories: high, medium, low)
- AGE_FIN - age of finish of the highest education (6 categories: aged 15 or younger, aged 16-19, aged 20-24, aged 25-29, aged 30-34, aged 35 or older)
- AREA_STUDY - are of study of the respondent's highest qualification
- LEARN_ACT_LY - (number of learning activities last year, 5 categories: no learning activities, one learning activity, more than one, respondent reported learning activities but number is not known, information on learning activities is not known)
- ACTIVITY_SPEC - the specification of the learning activity last year (4 categories: a course conducted through open or distance education, a seminar or workshop, an organized session for on the job training or training by supervisors or co-workers, other kind of course or private lesson)
- JOB_REL - the learning activity last year related to job (2 categories: yes, no)
- JOB_USEFUL - how the learning activity last year was useful for job (4 categories: very useful, moderately useful, somewhat useful, not useful at all)
- ACT_W_START_NO - there are some learning activities, which respondent wanted to start but did not (2 categories: yes, no)
- LIVING_PAR - living with spouse or partner (2 categories: yes, no)
- WORK_PAR - working situation of spouse or partner (9 categories: student, apprentice or internship, full-time employed (self-employed, employee), part-time employed (self-employed, employee), fulfilling domestic tasks or looking after children/family, in retirement or early retirement, permanently disabled, unemployed, other)
- CHILD_NUM - number of children (4 categories: 1, 2, 3, 4)
- HOUSHOLD_PEOPLE - people in household (4 categories: 1, 2, 3 or 4, more than 4)
- EDUC_M_FG - mother's or female guardian's highest level of education (3 categories: ISCED 1, 2 and 3C short, ISCED 3 (excluding 3C short) and 4, ISCED 5 and 6)
- EDUC_F_MG - father's or male guardian's highest level of education (3 categories: ISCED 1, 2 and 3C short, ISCED 3 (excluding 3C short) and 4, ISCED 5 and 6)
- REGION - geographic region in the Czech Republic (8 categories: CZ01, CZ02, CZ03, CZ04, CZ05, CZ06, CZ07, CZ08)
- EDWORK - interaction between adults' work and education status (5 categories: in education and work, in education only, in work only, not in education or work and has not participated in education or training in last 12 months, not in education or work but has participated in education or training in last 12 months)
- READYTOLEARN_CA - Index of readiness to learn (6 categories: lowest to 20%, more than 20% to 40%, more than 40% to 60%, more than 60% to 80%, more than 80%, all zero responses)
- ICTHOME_CA - Index of use of ICT skills at home (6 categories: lowest to 20%, more than 20% to 40%, more than 40% to 60%, more than 60% to 80%, more than 80%, all zero responses)
- INFLUENCE_CA - Index of use of influencing skills at work (6 categories: lowest to 20%, more than 20% to 40%, more than 40% to 60%, more than 60% to 80%, more than 80%, all zero responses)
- NUMHOME_CA - Index of use of numeracy skills at home (basic and advanced) (6 categories: lowest to 20%, more than 20% to 40%, more than 40% to 60%, more than 60% to 80%, more than 80%, all zero responses)
- WORK_PAID_YEARS - years of paid work during lifetime (9 categories: no years of paid work, two or less, more than 2 to 5, more than 5 to 10, more than 10 to 15, more than 15 to 20, more than 20 to 30, more than 30 to 40, more than 40)

- START_AGE - age of starting of work for employer (current work) or starting work for business (current work) (9 categories: aged 19 and younger, aged 20-24, aged 25-29, aged 30-34, aged 35-39, aged 40-44, aged 45-49, aged 50-54, aged 55 or older)
- ECON_SECTOR - economic sector (3 categories: a non-profit organization, the private sector, the public sector)
- IND_MANAGE - managing other employees (2 categories: yes, no)
- EMPLOYER_WORK_NUM - amount of people working for employer (5 categories: 1 to 10, 11 to 50, 51 to 250, 251 to 1000, more than 1000)

In case of the labels: "Valid skip", "Don't know or "Refused" the category "miss" was introduced.

Methodology

Boosting is one of the most powerful machine learning technique for classification and regression problems. Boosting works in a similar way as Bagging, but comparing to it where each tree is built on a bootstrap data set independent of the other trees, in case of Boosting the trees are grown sequentially, which means that each tree is grown using information from previously grown trees. Instead of bootstrap sampling in Boosting each tree is fit on the modified version of the original data set. Boosting involves combing a large number of decision trees. The tree is fitted using the current residuals rather than the outcome. In the current model the decision tree is fitted to the residuals from the model, then the new decision tree is added into the fitted function in order to update the residuals. In boosting the construction of each tree depends on the trees that have already been grown. (James, G., Witten, D., Hastie, T., Tibshirani, R., 2013, p.321)

Boosting has the following tuning parameters:

- the number of trees (*n.trees*)
- the shrinkage parameter (λ). This controls the rate at which boosting learns.
- *interaction depth* - the number of splits at each tree, it controls the interaction order of the boosted model.
- the number of observations in leaves (*n.minobsinnode*) - the minimum number of observations in trees' terminal nodes.

Let y is a response variable and $\mathbf{x} = \{x_1,...,x_n\}$ is vector of explanatory variables. $\{y_i, \mathbf{x}_i\}_1^N$ is training sample of known (y, **x**) values. The aim is to find a function $F^*(\mathbf{x})$ that maps **x** to y, so that over the join distribution of all (y, **x**) values, the expected value of some specified loss function $\Psi(y, F(\mathbf{x}))$ is minimized (Friedman J., 1999)

$$F^*(\mathbf{x}) = \arg\min_{F(\mathbf{x})} E_{y,\mathbf{x}} \Psi(y, F(\mathbf{x})).$$

Boosting approximates $F^*(\mathbf{x})$ by the "additive" expansion of the form

$$F(\mathbf{x}) = \sum_{m=0}^{M} \beta_m h(\mathbf{x}; \mathbf{a}_m),$$

where the functions $h(\mathbf{x};\mathbf{a})$ ("base learner") are usually chosen to be simple function of **x** with parameters **a.** For $m = 1, 2, \ldots, M$

$$(\beta_m, \mathbf{a}_m) = \arg\min_{\beta,\mathbf{a}} \sum_{i=1}^{N} \Psi(y_i, F_{m-1}(\mathbf{x}_i) + \beta h(\mathbf{x}_i, \mathbf{a}_m))$$

and

$$F_m(\mathbf{x}) = F_{m-1}(\mathbf{x}) + \beta_m h(\mathbf{x}; \mathbf{a}_m).$$

The algorithms of Gradient boosting and Stochastic gradient boosting can be found in (Friedman J., 1999) and (Friedman J., 2001).

Variable Influence

Consider that the tree has *L* splits. The influence of the variable *j* in a single tree *T* can be defined as (Natekin A., Knoll A., 2013)

$$Influence_j(T_i) = \sum_{i=1}^{L-1} I_i^2 1(S_i = j)$$

The measure is based on the number of times a variable is selected for splitting.

The overall influence of the variable *j* in the ensemble can be calculated as (Natekin A., Knoll A., 2013).

$$Influence_j = \frac{1}{M} \sum_{i=1}^{M} Influence_j(T_i).$$

Empirical Modeling

In the empirical part the factors that may have an impact on the differentiating of the high earnings from the middle and low monthly remunerations are examined in two segments: employees who are at managing position and employees who are not at the managing position. All calculations were done in R Studio.

Fig 1 shows the distribution of the monthly earnings including bonuses for wage and salary earners and self-employed, PPP corrected $US with corresponding median for the employees who manage other employees and for those who do not.

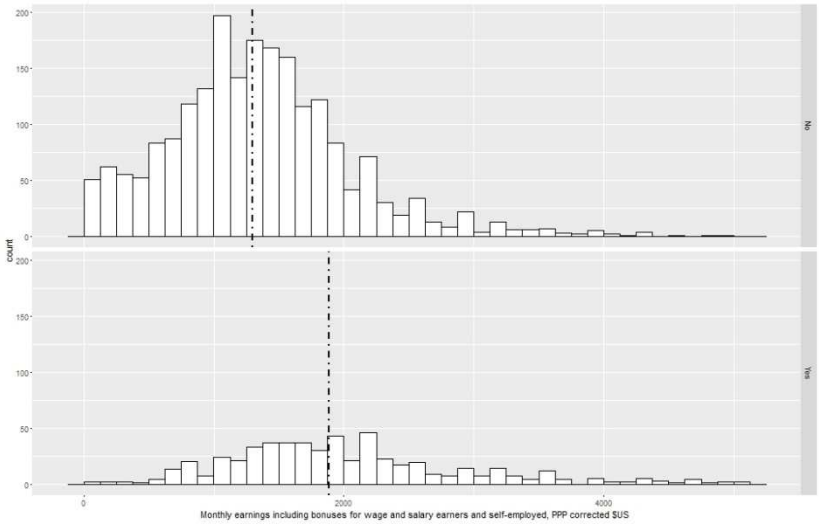

Fig 1. Distribution of the monthly earnings including bonuses for wage and salary earners and self-employed, PPP corrected $US for the employees who managing other employees and for those who do not. Own calculation in R Studio, *ggplot2* package. Data source: PIAAC.

According to the methodology part the Stochastic Gradient Boosting approach was applied. In R Studio the calculations were performed by using *caret* (Kuhn M. et al., 2016) and *gbm* (Ridgeway G., 2015) packages. Firstly, the stratified random split of the data was performed, where in case of the first segment (employees at the managing positions) 80% of data were allocated to the training set and the rest 20% create the testing set; in case of the second segment (employees not at the managing position) 75% of data were allocated to the training set. In order to avoid over-fitting and find the reproducible structure in the data, the resample techniques have been used. For both segments 5 repeats of 10 cross-validation and tuning parameter grid was specified as:

- *n.trees* from 100 to 1000, step is 100
- *interaction depth* - equality to 3, 5 or 9 was examined
- the *shrinkage* parameter (λ) was set equal to 0,001
- *n.minobsinnode* was set equal to 10

The optimal model has been chosen based on *ROC* metric.

Before applying the Stochastic Gradient Boosting technique the data preprocessing was performed. Firstly, the factor variables have been dummified, the "near-zero-variance" predictors have been eliminated prior modeling.

Employees, managing position

As it was stated above the optimal model was used based on the ROC metric using the largest value. The final values of the tuning parameters used in model are: *n.trees* = 1000, *interaction depth* = 5, *shrinkage* = 0,001 and *n.minobsinnode* = 10. The model's evaluating was performed using the data allocating in the testing set based on the AUC value. AUC is equal to 0,7304.

Based on the final model's results the variables, which have been indicated as the most important, are the shown at Fig 2.

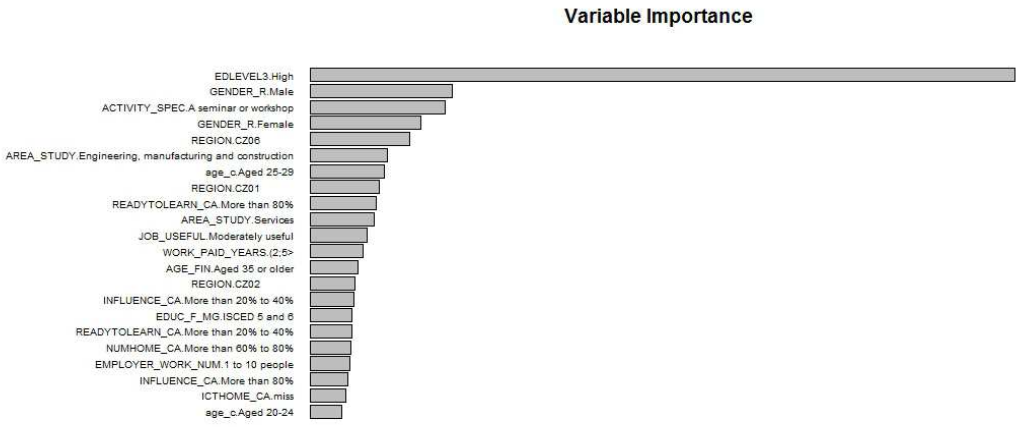

Fig 2. Variable importance based on the Stochastic Gradient Boosting model (employees are at the managing position). Own calculation in R Studio, *caret, gbm* packages. Data source: PIAAC.

Based on the results (Fig 2) in case of the employees at the managing position the greatest impact on the differentiating the high level monthly earnings from the middle and low ones is the indicator of the high level of education. Gender also plays a significant role. Fig 3 shows the distribution of the outcome variable (*High*) for the different levels of education for male and female separately.

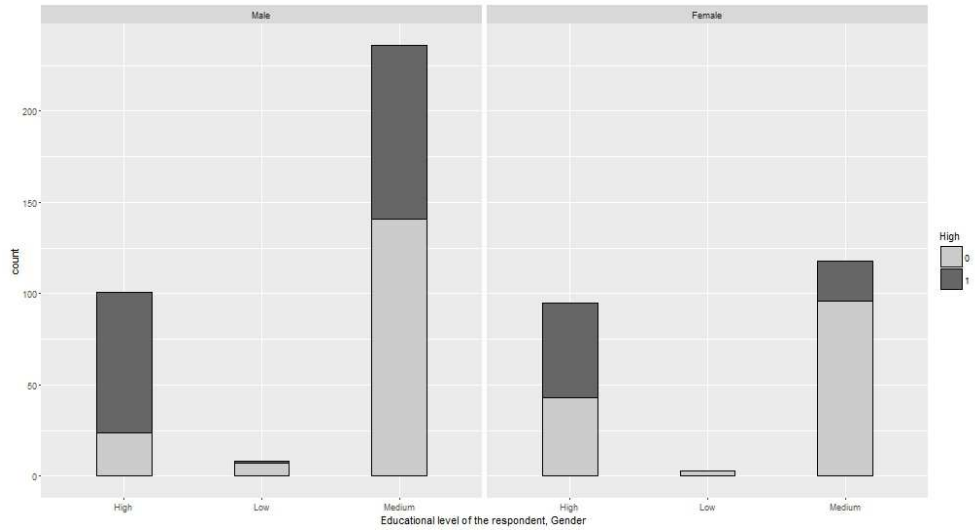

Fig 3.Distribution of the outcome variable (*High*) for different level of education for male and female. Own calculation in R Studio, *ggplot2* packages. Data source: PIAAC.

Based on Fig 3 it can be noticed that for both male and female employees at the managing positions the prevailing proportion of employees with high level monthly earnings is in the high education level category, but in case of male employees this proportion is higher (76%) than in case of male employees (55%) .

The distribution of the outcome variable in case of area of study (chosen categories with biggest representation) of the respondent's highest qualification for male and female can be observed at Fig4.

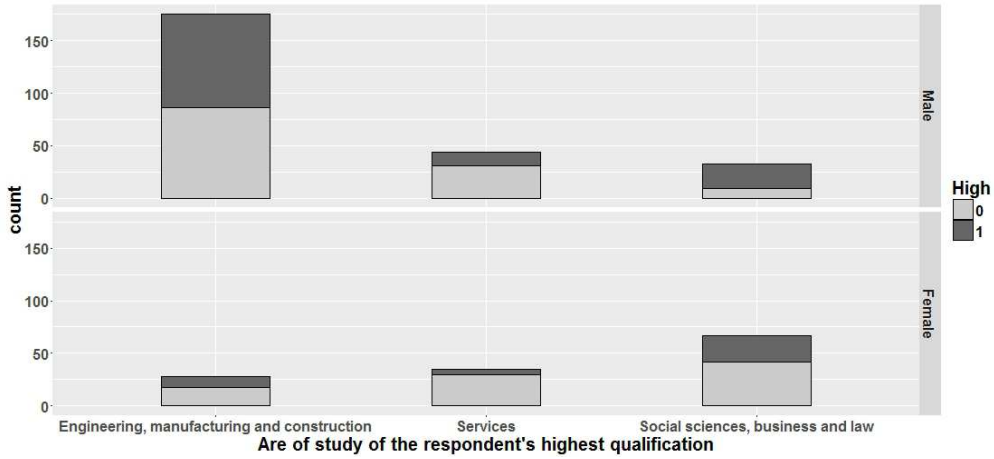

Fig 4.Distribution of the outcome variable (*High*) for the chosen areas of study. Own calculation in R Studio, *ggplot2* packages. Data source: PIAAC.

It can be observed that for male the category *Engineering, manufacturing and construction* has the biggest absolute representation comparing to others categories and in this category for male employees the proportion of employees with high level monthly earnings is 51% ,while for the female employees it is equal to 36%; for female the category *Social sciences, business and law construction* has the biggest absolute representation in this category for female employees the proportion of employees with high level monthly earnings is 37% ,while for the male employees it is equal to 73%.

According to the model's results (Fig 2) personal and professional kills measured by different indices are also among the most important variables.

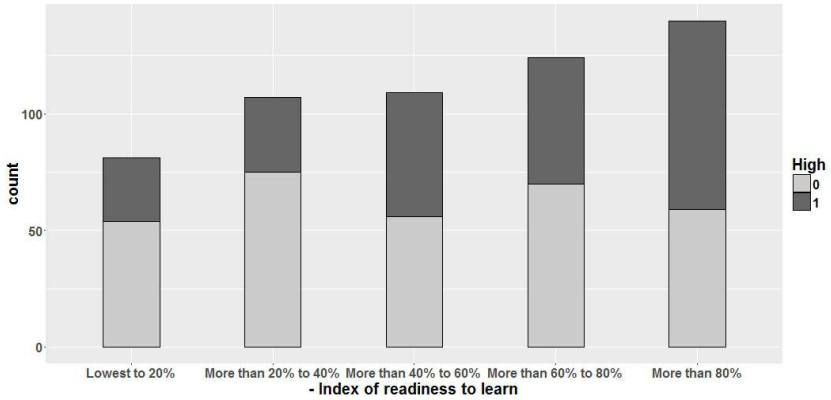

Fig 5.Distribution of the outcome variable (*High*) for different categories of Index of readiness to learn. Own calculation in R Studio, *ggplot2* packages. Data source: PIAAC.

Looking at Fig 5, it can be seen that employees at the managing position with high level of monthly earning are most relatively represented in the last category (more than 80%). In case of indices of using numerical and ICT skills at home the greatest relative representation of the employees with high level earnings is for the highest categories (more than 60% to 80% and more than 80%).

Based on the results provided by the model it can seen that the learning activity last year (category: *seminar or workshop*) plays also a significant role in the differentiating the high and other levels of monthly earnings. Ragionality plays also a significant role in the differentiating between the high level of monthly earnings and other levels. The greatest representation employees with outcome value equal to 1 is in Prague and Stredni Chechy region.

Employees, no managing position

The final values of the tuning parameters used in model are: *n.trees* = 1000, *interaction depth* = 9, *shrinkage* = 0,001 and *n.minobsinnode* = 10. The model's evaluating was performed using the data allocating in the testing set based on the AUC value. AUC is equal to 0,8176.

Fig 6 shows the most important variables based on the final model's result.

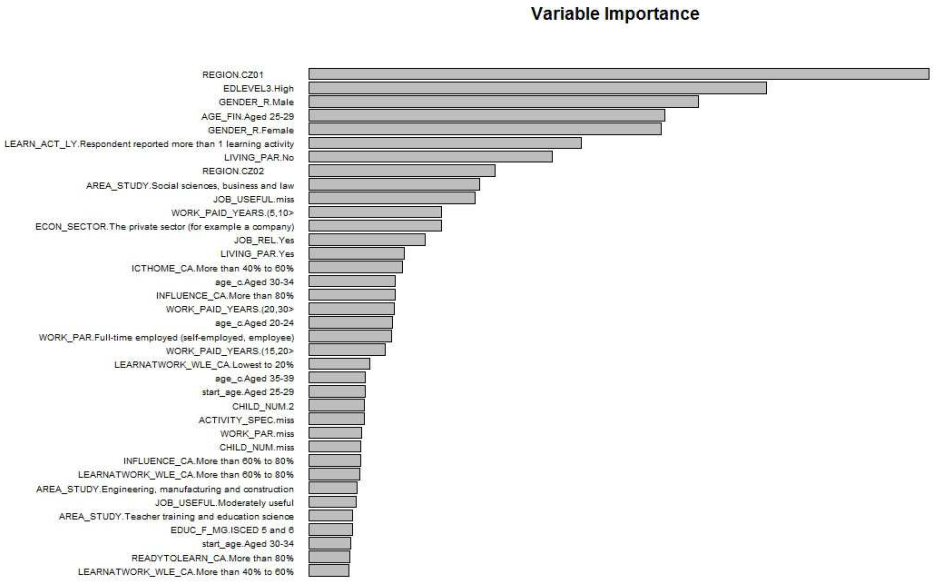

Fig 6. Variable importance based on the Stochastic Gradient Boosting mode (employees are not at the managing position). Own calculation in R Studio, *caret, gbm* packages. Data source: PIAAC.

Based on the Fig 6 it can be noticed that in case of the employees who are not at the managing position the ragionality plays a significant role as well in the differentiating the high levels of monthly salaries from middle and low levels. Similarly to the segment of the employees at the managing positions Prague and Stredni Chechy have the major share of the employees with high earnings. As well as in the previous model high level of education, gender, learning activities, area of studying, indices of readiness to learn or using ICT skills at home are important in the differentiating between high and middle with low monthly earnings. Looking at the distribution of outcome for the different categories of the father's or male guardian's highest level of education (Fig 7 and Fig 8) for two segments (employees are at the managing position and employees who are not), it can be observed that for both segments the major relative representation the outcome with value equal to one is in case of the category OSCED 5 and 6, but for employees at the managing position the share of employees with high level salaries exceed the employees with middle and low salaries in the category of OSCED 5, 6 of the father's or male guardian's highest level of education.

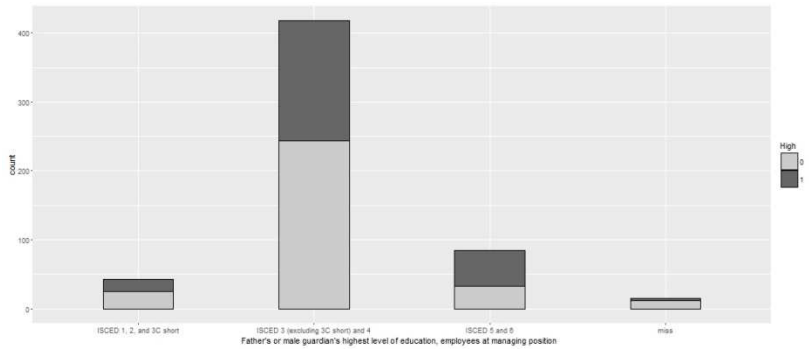

Fig 7.Distribution of the outcome variable (*High*) for different categories of father's or male guardian's highest level of education, employees are at managing position. Own calculation in R Studio, *ggplot2* packages. Data source: PIAAC

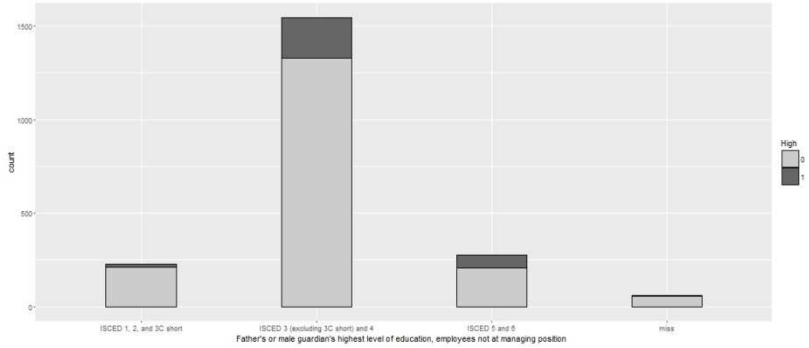

Fig 8.Distribution of the outcome variable (*High*) for different categories of father's or male guardian's highest level of education, employees are at managing position. Own calculation in R Studio, *ggplot2* packages. Data source: PIAAC

Analyzing the demographic features also provides the interesting findings. In table 1 there are proportions of the categories of outcome variable for different categories of number of children for both segments. It can be noticed that in case of managing position the category of 2 children has the highest relative representation while for employees who are not at the managing position this category is the second after the category of "no" children.

Table 1 Proportion of the outcome's categories for different categories of number of children

Number of children	Manag.position (y =0)	Manag.position (y =1)	No.Manag.position (y =0)	No.Manag.position (y =1)
1	0,188	0,162	0,164	0,200
2	0,408	0,441	0,343	0,321
3	0,073	0,113	0,079	0,053
4	0,025	0,037	0,035	0,026
no	0,306	0,247	0,379	0,400

Conclusion

The current paper examined the factors that have an impact on the differentiating of the high earnings from the middle and low monthly earnings in the Czech Republic. As a high level monthly earnings were considered the earnings which are equal or exceed 2000 USD. The analysis was performed separately for two segments: for employees at managing position and employees who are not at the managing position. The main data source was the Survey of Adult Skills (PIAAC). The analysis was conducted with the use of Stochastic Gradient Boosting approach. For both segments such variables as: level of education, gender, regionality, area of study, learning activities, index of readiness to learn and index of using ICT skills at home play an important role in the differentiating between the high monthly earnings and middle or low earnings. The father's or male's guardian highest education (category: OSCED 5 and 6) is among important variables for both segments as well, but in case of the employees at the managing position the share of high level earnings in this education category (OSCED 5 and 6) exceeds the share of middle and low earnings.

Consumer Behavior in the Banking System. Romania's Case on Real Estate Loans

Cheptea Mădălina, Bucharest University of Economic Studies, Bucharest, Romania,
madalinacheptea@gmail.com

Bodislav Dumitru-Alexandru, Bucharest University of Economic Studies, Bucharest, Romania,
alexandru.bodislav@infinitumgroup.com

Abstract

This research paper represents the highlights found in a study done by using a questionnaire in trying to reach the level of adversity towards risks on contracting a real estate loan, the level of knowledge and understanding had on the way financing tools work when it comes to loans and the perspective towards were does an emerging economy situates itself, in this situation being the case of Romania.

The main goal of the study was to observe if something changed in their behaviour during these years of economic and social turmoil and to highlight an answer to broad question: how do Romanians react and quantify the risk had by a real estate loan or investment? The dynamic answer given to this question resulted by using an online questionnaire that had 1214 respondents between December 2015 – February 2016. The data that resulted is explained here with the purpose to map how Romanian's economically feel were they are heading and to better understand what are their main concerns regarding their expectations and motivations.

Keywords: consumer behavior, real estate loans, interbank interest rate, banking system

Introduction

In the years following the economic crisis businesses went bankrupt and with them the lives of those owning the businesses or employed at those companies. For those that went on and reached their potential in other jobs, nothing changed, but for those that remained unemployed there was some pressure developed, reaching their basic needs each day, and in Romania's case, for 800.000 of them, reaching the ability to pay their mortgages and loans.

To better understand the social pressure developed by not paying your loans we will present both sides, the banks that offer loans, the population that borrows, but both sides are regulated and shaped by the National Bank of Romania and the Romanian Parliament.

The social pressure – unchained

Radu Ghetea, Honorary President of the Romanian Association of Banks and the President of CEC BANK, a state owned bank in Romania, declared in 2015: "If You have taken something as a loan, You have to take it back. So, no one should imagine that s/he will get rid of the debt: s/he will either go to prison for the debt, or all his/her goods will be taken." Such a declaration form the part of a bank official may create frustration on the bank customers.

In Ancient Rome, the people that were in a state of bankruptcy were killed and cut into as many pieces as the number of creditors s/he had, and each creditor took a piece (Bodislav, Cheptea, 2011).

In the Middle-Eve, the so-called pillory was used for blaming the people that are in debt, and there was a practice to blame the debtor in the public square and also the debtor was exposed on the streets. There was also a "debtors' prison", where family heads were incarcerated.

Romania had also a "debtors prison", that was regulated in the 1864 civil code, but over the years it has changed, from killing the debtor to giving him/her a second chance in 2014, through the law of personal bankruptcy.

In November 2015, 800.000 Romanians, were fighting bank instalments, facing great difficulties in paying them, being placed under terror by private credit collection enforcers or bank officers.

The sad part of the story

Furthermore, we will present some social cases developed by the inability to cooperate with the banking system and the inability of the state to intervene and protect its citizens against themselves (Geltner, et al., 2013) when it comes misfortunate situations of poor financial investment knowledge (Munneke, Womack, 2016). 32 people have committed suicide because of high debt, and we'll present some of the cases in the following pages (their names aren't written due to psychological reason regarding their families):

1. Emanoil O. took a loan in 2008, when he had wage of 15.000 RON, in 2010 became unemployed because of a management problem facing the worldwide crisis, he had a monthly 1752nstalment of 5000 RON and his house and mother's house placed as guarantees in the bank's favour. The currency was the loan was CHF, namely Swiss Francs. Emanoil hanged himself not being able to accept the bank's harassment. He left behind 2 children, one of 2 years and another of 4 years old, a homeless mother and a homeless wife. Emanoil's family accuses that the moral authors of the suicide are the bank. Through the procedure of sending notifications, raising penalties and interest rates, plus the situation of the bank instalments, had brought the 2 husbands on the verge of divorce.

A simple simulation of CHF credits shows as follows:

In the table below will show the increase of CHF versus RON, yearly.

Table 1: A simulated credit between two currencies: RON (Romanian Leu) and CHF (Swiss Franc)

YEAR	CHF ~ RON exchange rate	RON Credit Value for 300CHF	Increase in % compared to 2008
2008	2.2	660	-
2010	2.8	840	27%
2011	3.3	990	50%
2012	3.6	1080	63%
2013	3.6	1080	63%
2014	3.7	1100	68%
2015	4.2	1260	90% more.

Source: authors own calculations.

1. A man of 34 years old from Pitesti, who's wife has left him because of misunderstandings created by the difficulties of paying the monthly instalments, has committed suicide. Moreover, the daily tensions and stress related to their current situation had driven the man on the verge of hitting his wife. Although the neighbours and friends have confessed regarding the 2, that they were an extraordinary perfect family, the daily issues have led the 2 on offending, hitting, molesting and ultimately divorcing each other. The P. family, as they were called a 3 years old boy and a CHF loan contracted in 2007.

2. A policeman of 30 years old from border police of Sannicolaul Mare, northern area, has committed suicide, after his food compensation implied by his job was cut-off,

and he became unable to pay the 2000RON monthly instalment. He had passed all his psychological tests prior to the event. He had a 7 years old daughter.

3. A man of 41 years old hanged himself by the stairways that led to the terrace of the building he lived on. His family declares that the man was terrorised by the phone calls the bank used to give him every week, different numbers. Their problems as a family not being able to repay the debts, have began when the man's wife fell severely ill, lost her job in the meantime, and they became unable to repay the loans.

4. A 24 years old committed suicide for not being able to pay a loan taken, in the equivalent of 700 euros, for buying a television. He had a 400 RON wage, a wife, a 7 months old child and 2 parents to take care of. The man has been described by his fellow workers as being honest, positive, trustful in the future, and none of them justifies his gesture.

5. Ion I., 53 years old has committed suicide because of the bank's inflexibility, that had all his goods executed over the debt of the company he owned. He shot himself in the heart.

6. Emeric H., 44 years old, from Arad, hanged himself, for not being able to pay his personal debts. Friends had shown that his honesty was way higher than was thought to believe, fact that his taxi company, prosperous, never got robbed to repay the banks.

7. Ion G., 55 years old, has committed suicide after the banks had executed his home, after losing his job, not being able the repay the debt, and by bank's fault of not processing an unemployment insurance. The bank, after executing the house, went further and pushed him to pay leftover amount remained from not covering the debt. He hanged himself in the small room, his former working colleagues had given him as a place to stay.

8. Mircea B., 49 years old, father of 3 children, 2 of them underage, an agent of the public order and protection institution, has shot himself with the working gun, not before calling his 22 years old son, to tell him that he does not foresee any solution regarding the bank debts.

9. Gheorghe P., 41 years old, a heavy machine operator had a working accident, that led to 100 days in a hospital and a major cut in his wage. He found himself in the impossibility of paying the bank loan, he did a big mistake and asked the help of loan sharks. When things gone completely mad, he decided to commute suicide, his wife has remained to deal with the bank and also the loan sharks.

10. Eugen C., from Galati, 34 years old, has jumped over a bridge after the bank has executed his parents house, and got close to execute his grand parents house, as endorsers of his loan. He had a 3 years old daughter.

11. A very interesting case is the case of the woman from Cluj-Napoca, who has won the trial against the headquarter of a bank. The bank used to call the woman's house, sometimes when she was not at home, talking with the woman's 9 years old daughter and threatening that the family will end up on the streets. This was done repeatedly, and with the consent of the bank's procedure, the child now needing therapy.

32 people have committed suicide during the last years, due to unregulated market problems regarding exchange rates skyrocketing too fast, too soon, with no control by the authorities. All the

cases incumbing monthly instalment payments led to a hysteria, permanent fights and tensions, among husbands, and ultimately divorce.

The children with parents that have committed suicide are dealing with serious psychological issues, some of them being inside state social security system. According to the child's age the effects the debt of one of his parents may become an event that will trace his entire life. The remaining parent, caught in his own emotions, may ignore the child's needs and feelings.

Among the psychological effect of a parent's death over a child, may be: depression, insomnia, nightmares, a behavioural regression like talking problems, peeing in bed, losing appetite, anxiety, guilt feelings, memory loss, hyperactivity, learning difficulties, introvert behaviour. Small children manifest their feeling through developing disease.

The law of giving into payment so much disputed this days, and so much contested by the banks, has proven the truth face of the financial institutions, interested exclusively into profit, no matter the means.

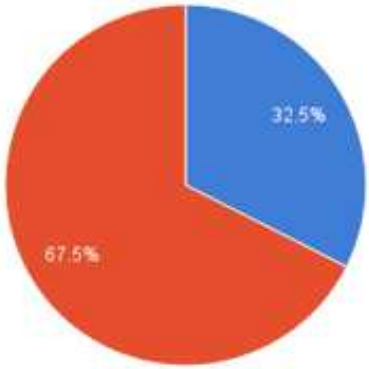
In the equation profit vs. humanity, the banks always go with the profit, leaving behind, broken lives, broken families, wing-cut children facing a gloom perspective over life (Norhtcraft, Neale, 1987). The 32 tragedies and the following ones, could have been avoided by having a constructive perspective over business and human lives (DiPasquale, Wheaton, 1996). Short term solutions are not so difficult to be found. The state must have an active attitude towards these matters protecting his citizens.

Where are we now?

After almost 8 years of social turmoil and acknowledging that the banking system is for those that have better knowledge of their savings and consumption mechanism we will present the results of a study done between December 2015 and February 2016 on a pool of 1214 respondents by using an online survey which was sent towards acquaintances and to "cold pool" of unknown subjects. The purpose of the study was to observe if something changed in their behaviour during these years of economic and social turmoil and to highlight an answer to broad question: how do Romanians react and quantify the risk had by a real estate loan or investment?

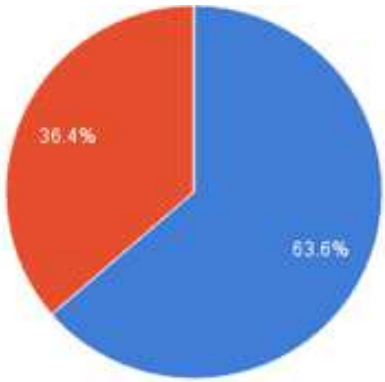
We'll have to state that 61.4% of our respondents where women and 38.6% men, with age groups divided with a bias towards that are between 25 and 35 years old (38.1%) and 35 to 45 years old (31.3%), these two age groups are important because they are main clients for buying a small apartment of their first apartment/house, the first group, or they are searching for something bigger to settle and prepare for their elderly times, the second group. Regarding their studies, those that have only graduated from high school or less are in a minority (less then 13.3%), so the level of knowledge on the domain should be above average. When it comes to their employment status, our respondents are most of them occupied (employed, entrepreneur or student total up to 82%). Almost half of them are owners of their houses/apartments, but almost a quarter still live with their parents, the rest are paying a monthly rent. Regarding their available living space/per person, we can say that 57% of them live in a space between 15 to 30 sqm/person. One interesting fact is that more than half of them don't have any children (54.6%) and slightly over 50% aren't married (50.6%). When it comes to their monthly revenues, almost half earn less than 2500 lei (the equivalent of 550 euro), a quarter of them between 2500 lei and 4500 lei (equivalent of 1000 euro).

After the part that socially scales our study, we can go further and evaluate how are they in line with how they behave from their financial perspective, or on how they decide to buy a house/apartment.



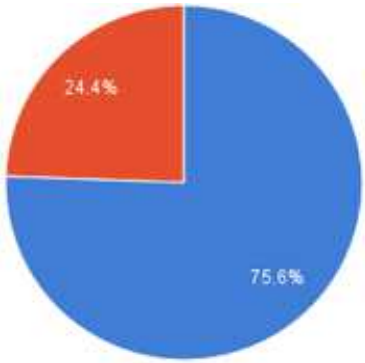
67.5% answered YES, 32.5% answered NO

Fig 1. Are you afraid of a decrease in your monthly income and the ability to contract a real estate loan?



63.6% answered YES, 35.4% answered NO

Fig 2. Are you afraid of a future unemployment situation in the ability to contract a real estate loan?

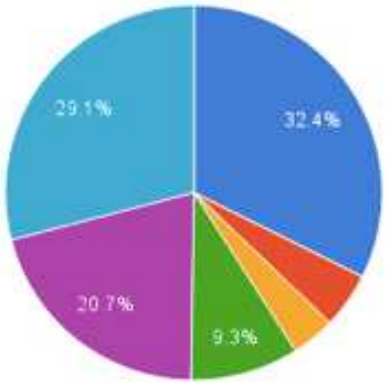


75.6% answered YES, 24.4% answered NO

Fig 3. Is the level of your monthly income so low that you cannot contract a real estate loan?

From these 3 direct questions regarding our subject we can observe the adversity towards the idea of contracting a real estate loan. Most of the respondent's fears are based on the fact that they aren't expecting any improvements of the global economic situation in general, and especially they aren't fond of the actual and the trend of the Romanian economy, they aren't sure about their future and about their financial well being, but the large majority isn't able to contract a real estate loan, so there is a long way until they'll buy themselves a house/apartment (similar findings, but on the entire economy of Romania, we'll find in Dinu, Bodislav, 2015). During the study we also asked the respondents if the exchange rate and the inflation rate would scare them in not to contract a real estate loan, but the answers were around the 50% threshold for each them, with a slight advantage towards Yes for the exchange rate (50.7%) and No for the inflation rate (53%), the latter one being more dangerous than the first one if we filter the thought process through a macroeconomic perspective.

In Figure 4 we can observe what is most frightening for the respondent and what stays in his path to be happy.



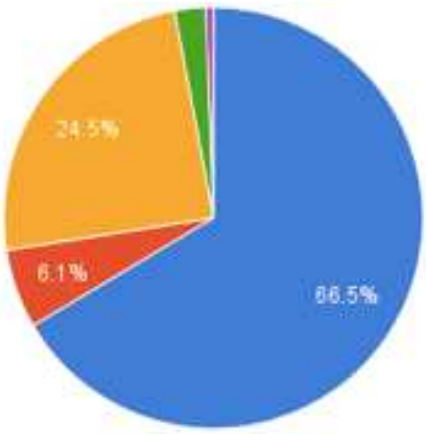
32.4% - Income level, 29.1% - Unemployment, 20.7% - A drop in income level, 9.3% - Corruption, 4.5% - Inflation rate, 4% - The exchange rate.

Fig 4. What frightens you the most?

Our first three questions regarding the subject of our research 82.2% of the worries of our respondents, so we could state that these areas need to be enlightened and reformed by legislators and filtered positively by the banks.

The willingness to own a house or an apartment is huge, almost 94% of the respondents answered yes to this question, but only 74% would buy that home though a loan, the difference of 20% are the mass that we can say it is afraid of the future, they don't trust the employers, the banks, or even the legislators.

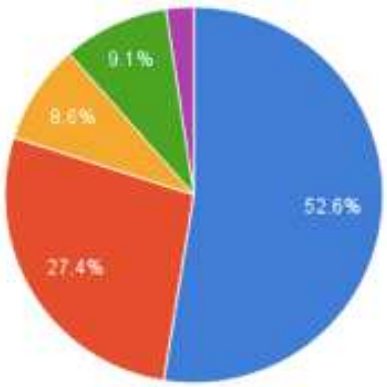
To evaluate their behaviour towards taking a real estate loan that could endanger them into being unable to repay it, we introduced three questions:



66.5% - answered that they don't want a reduction of the down payment to receive a higher interest rate
24.5% - answered that they would accept this measure, if the interest rate will be linked with the interbank rate (robor) plus 5 percentage points
6.1% - answered that they would accept this measure, if the interest rate will be linked with the interbank rate (robor) plus 3 percentage points
2.9% - were divided between accepting the offer and having an interest rate with 5 to 10 percentage point higher than the interbank interest rate (robor) and also said yes for an offer with an interest rate with maximum 2 percentage points above the interbank interest rate (robor)

Fig 5. If money isn't an issue for a down payment to buy a house/apartment through a loan, would you accept a higher interest rate and having a smaller down payment?

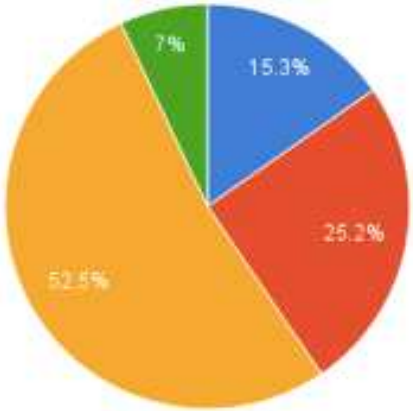
From this question we understand that the adversity towards a risky future is still present, that is why two thirds wouldn't accept the offer, but the others, especially those 24.5% would accept an offer that would double their monthly instalments, because today in Romania, the ROBOR is around 0.85% and banks offer real estate loans with a margin of 2 to 3 percentage points over the robor, so if the respondents had knowledge about the market they would have answered in a higher number for lowest voted solution or at most for the one chose in only 6.1% cases.



52.6% - answered maximum 3 years above
27.4% - answered between 3 to 5 years above
9.1% - answered between 7 to 10 years
8.6% - answered more than 10 years
2.3% - answered between 5 to 7 years

Fig 6. If you are buying a house/apartment through a loan and you are able to increase your real estate loan's lifespan over your pension age (63 yrs – women, 65 yrs – men), how many years you would go above?

This question was developed to see if the respondents are able to process the fact that they can go further then their retirement age, but played it safe by choosing 80% to a maximum 5 years of prolonged debt.



52.5% - answered maximum 30%
25.2% - answered maximum 50%
15.3% - answered maximum 40%
7% - answered maximum 60%

Fig 7. If you are buying a house/apartment through a loan and you are able to set a maximum threshold as a percentage of your monthly income, what would that be?

It is clear that Romanian's still fear the future from the economic perspective because they chose as main answer a level of monthly instalments of maximum 30% which means that they are more cautious than the actual banking system that goes to a level of 33.3% the level of monthly instalments, and for the bank employees could reach 50% the level of monthly instalments compared with the monthly income. More than 40% of the respondents went on the idea that they should reach

a level of 40 to 50% in the level of monthly instalment, fact that shows us that there is an important pool of people that are willing and hungry to have a moderate risk to reach their Nirvana, buying and owning a home.

Conclusion

We can observe that Romania's economy isn't well prepared for economic crisis, be it a tangential one. Its public institutions, its legislators and the banking system need some fine tuning at least, because they should protect the market place through a soft proactive manner developed by using knowledge, know-how and legal injections in the system.

From our study we understand that Romanian's afraid of the ability to contract a real estate loan and not being able to repay it, this fear being doubled by their lack of knowledge when it comes to understanding the banking system and how loans work. The entire study offers us a counterpart to the first part of the paper were we presented the macro-social case, the sad stories of those that lost their homes and some of them their lives. There is hope in reaching Nirvana, buying and owning a home, but the path to reach that goal is as close, but yet so far for those that aren't mentally and financially prepared for the road they part on.

Influence of Innovation Management on Project Management in an Organization

Blanka Bazsová, VŠB-Technical University of Ostrava, Ostrava, Czech Republic,
blanka.bazsova@vsb.cz

Abstract

Innovation is a phenomenon of nowadays and inevitable activity of any company which strives for success. The innovation activities require skills of strategic thinking, system approach and financial management with very strong proactive approach and customer orientation. Most of innovation activities are implemented as a project. For a successful project it is important to the organizational structures. The objective of this article is to identify and determine the importance of different factors influencing the organizational structure.

Key words: ICT, innovation, organizational structure, project

Introduction

In broad context, innovation is one of indicators of measurement of competitiveness level. Innovation can significantly contribute to the increase of organization's revenues, to achievement of its strategic objectives, to product quality improvement, to customer satisfaction, to better satisfaction of customer needs, to market position improvement. The role of organization's management supporting innovations consists in identification of opportunities which are connected with the company success and influence its competitiveness in the market. Analysis and improvement of these opportunities are a result of scientific and research activities of the company. They are an outcome of efforts to be an active player in the market and response to changes in external conditions. Innovation is implemented typically using a project. The project success depends on the project management and organization. These factors are shown in fig 1. Each project is organized in certain way, necessitates a specialized expert team led by an experienced project manager and is demarcated by budget, defined target and allocated funds. The team can be made up both of existing working positions and new positions requiring specialization for successful implementation of the project.

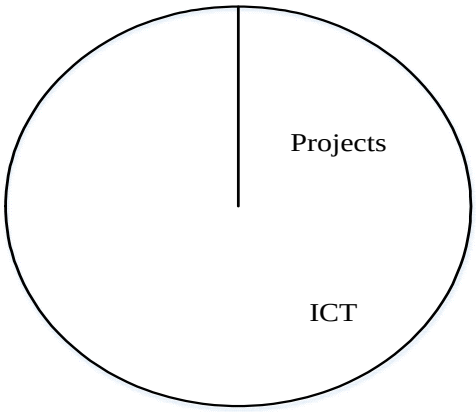

Fig 1. Key innovation factors

Utilization of projects for improvement of the company position requires definition of implementation methods and procedures in the form of innovation strategy. The innovation strategies are built on introduction of changes in internal environment of the company which will lead to the desired modification of its entrepreneurial behaviour (Pitra, 2006).

The opportunities for innovation can be (Pitra, 2006):

1. Manufactured products or product series;
2. Customer and its preferences;
3. Influence of information technologies and technological development;
4. Competitors and their competitive advantages.

It should be noted in relation to the opportunities for innovation listed above that, for example in case of products, value analysis can be applied to evaluate the different functions fulfilled by the product. This way their importance can be quantified and express the relation between the degree of fulfilment of function and costs associated with the function using the indicator of relative effective value. In European context, statistic data of EU countries can be retrieved to indicate the level of sales yielded by the innovated products as % of total sales (Eurostat, 2016)

As far as the customer preferences are concerned, it can be identified which products stand in the forefront of interest of the customer groups and based on it innovation concerning the additional services such as after-guarantee service, etc. can be made. The production process can also be restructured using process reengineering. This notion relates to Michael Hammer, a US professor at Massachusetts Institute of Technology, who expressed the idea of continuous improvement of processes with the view of performance improvement. Today certain level of support in the form of ICT is largely demanded. ICT can significantly affect daily operations and functions of the businesses and managers cannot imagine their decision making process without a use of information technology (Bazsová, 2013). The most conspicuous example might be sale of product through e-shop. Another example of opportunity for innovation may be introduction of performance management system using software application. It is also possible to focus on analysis of visit rate of web pages of the different products, etc.

Support of innovations

The support of innovation implementation using a project also entails certain unification (unique) effect in the form of managed project which consists of well-known phases – definition of project objective and purpose, specification of implementation means, implementation process and review.
Innovation activities cannot be implemented without financial support which cannot be inconsiderable. It is generally known that internal company funds are insufficient. For that reason companies have to try to obtain finance from the operational programmes or apply joint projects involved in contractual research. The innovation efforts often include cooperation with universities, research institutes or incubation centres. Support of innovative activities can be realized with support from the structural funds, where, in the framework of the Operational Programmes, to which the EU member states are involved, it is possible to receive subsidies, for example, under the Operational Programme Enterprise and Innovation (Czechinvest, 2016). The amount which a company can get is based on the level of support of the EU structural funds and partly on the state budget of the individual member countries.
Innovation activities are not supported only at national level but also at international level, as evidenced by challenges e.g. from the COST program, Eurostars, Eureka, Mobility, and more.

Innovation indicators measuring innovation level of countries were created to enable international comparison. The most commonly applied measuring indicators include research and development expenditures spent in different industries, number of issued patents, number of issued publications, number of researchers and the number of universities and postgraduate students. A possible tool for comparing the attractiveness of the European Union (28) countries in terms of their innovation potential and competitiveness is an innovation barometer (Jedlička and Macháček, 2015). The barometer is compiled from 9 monitored statistics that determine competitiveness, innovation potential and future prosperity of the country. This research was brought by many authors, for example Halásková and Halásková (2015).

Organizational innovations

Gunday et al (2011) state that organizational innovations are closely connected with administrative efforts to change organizational procedures, routines, mechanisms, systems, etc. (According to Zaied and Affes, 2015). Innovation results in change in creation of new models of organizational structures, new relations among members of personnel, changes in thinking of personnel and can also induce changes in business strategy of the company. As concerns the process reengineering mentioned above, the focal point is assignment of roles in the team composed of the process owner, team leader, facilitator, external consultant, coordinator and, if appropriate, other members and the following is necessary:

1. Determine the way in which the teams are to be made up and how the process is to be formalized. The establishment of implementation team is up to the managing director. The selection of team members depends on the order nature. A factor with important role in the selection of team members is competences. Competences can be divided into personal and specific ones. The personal competences include, for instance, people skills, negotiation skills, constructive discussion skills, etc. which are essential in decision making on admission of a member to the team. This will prevent unnecessary conflicts. The managing director assigns the order to the team leader and they select the team members together.
2. Determine decision making rights of the team members. The team leader clarifies the performance requirements for the different team members. Required time and project completion date are determined. The team leader also decides the order in which the requirements will be addressed.
3. Be informed on the project all the time. The team leader must be aware of the project progress all the time. The information must be provided by the team members. The team leader must know which sections have been finished, if the delivery dates are met and if the other conditions are met by external suppliers.
4. Method of integration into organizational structure. The implementation teams are integrated in the organization typically in the form of matrix organizational structure or purely project organizational structure. In case of matrix organizational structure a problem of double or multiple subordination of personnel has to be faced. Matrix OS has two groups of units - functional and target (project) oriented. The number of goal-oriented units corresponds to the number of projects that the organization implements. Functional units include specialization in economic, and also commercial and technical units. Functional units are generally subordinate to the director (manager) of the organization. Project managers, project engineers or project leaders are in the lead of the target (project) oriented units. The problem can be caused by overloading and excessive demands placed on the staff being members of several teams. In project oriented organizational structures an employee is often engaged in several teams. This type of structures is commonly seen in software oriented organizations. The advantage of this organizational structure is its flexibility and target-orientation; also main problems of the organization are addressed here. The disadvantage is a violation of a classic principle of single seniority. Another disadvantage is that the workers of the functional units are not or only partially released from their functions in the current organization.

Role of project manager as team leader

Nowadays is necessary to be able lead the professional group. If the company want to be innovative, it should support project managers and develop their competencies. The project manager receives and manages the work on project. He or she accepts the work taking into account its complexity as well as all other official requirements for the project. The project manager must be selected based on his or her experience in the concerned field. Certification of the project managers in the Czech Republic is the duty of the most famous standard and platform IPMA (International Project Management Association. Part of this standard is to define the requirements for the competence of the project managers and their teams. Within this standard, it is possible to obtain certification of the so called grades A – Certified Project Director, B – Certified Senior Project Manager, C – Certified Project

Manager, D – Certified Project Management Associate, which differ in skill requirements. According to IPMA standard, technical competence, both behavioural and contextual, are defined (Doležal et al, 2009).

In case of a production company the team leaders are selected typically from personnel from design, production, installation and inspection departments.
Tasks:

1. Creation of team – The team leader in liaison with the managing director makes up the team of employees who will be involved in the order execution. The team leader selects the candidates and the technical director approves their admission to the team based on assessment of their workload and any membership in other teams.
2. Project progress monitoring – An important of task of the team leader is to monitor the order execution to an extent enabling him or her to inform the customer or company management of the order execution progress at any time. The information is provided in the form of reports from the team members to the team leader. They include in particular summary of finished products and work-in-progress, and results of inspection analytically divided according to the different manufacturers and sub-suppliers.
3. Communication with sub-suppliers – The team leader orders a part of the work from external partner specifying the delivery and payment terms and required quality, if not stipulated in the contract. Further communication with the sub-supplier during the production related to normal production process and delivery of the required components is managed by a member of the inspection department staff.
4. Communication with customer – Communication with customer is one of the most important tasks of the team leader. He or she must be able to update the customer on actual situation and order execution progress at the customer's request at any time. It of great importance for the team leader to have communication skills allowing him or her to properly identify the customer's requirements and desires so that the customer satisfaction can be maximized. This task of providing the information to the customer can be fulfilled also by a member of the marketing department staff.

The organization currently faces the challenge to create a comprehenshive model of performance evaluation based on performance indicators balance and competency models. These indicators create assumptions for achieving the strategic objectives of the company. The unique combination of competencies forms the culture of an organization that promotes learning and education deemed as an important business process by the top-level and line managers that are committed to it and that are permanently engaged in it (Armstrong, 2009). In practice, a series of competency models was created (see fig 2). Most of them are based on three pillars - focus on the product, customer and service and system.

It is necessary to identify competencies and responsibilities, which have employees. Developing of the employees competences also becomes an opportunity for success and innovation process. The success of any project depends on the characteristics and experience of a project manager, i.e. on his/her competence. It is crucial to integrate PM into the organizational structures of companies. (Řeháček, 2015a). Among the important and currently widely used organizational structures that reflect the project design contract performance, include matrix organizational structure.

Matrix organizations try to use advantages of functional and projectized organizations and combining them into one. The project team is free to focus on the project objectives with minimal distractions from the functional department (Řeháček, 2015a). It is based on connection of existing jobs with the project structure. It consists of 2 teams - a team of existing functional departments and task-oriented team formations. Transitional design departments have the responsibility to tackle the project task. These units after completing the task expire. Vertical and horizontal organizational relationships often blend, when the worker is subordinate to the project and line manager (according to Řeháček, 2015b). The functional managers have all the power in this structure. Project office is among the permanent organizational structure (Doležal et al, 2007). It is used in the case the projects in the

organization cease to be in the minority. According to Doležal et al (2007) it should cover four main functions - definition, control, implementation and support.

The definition function is based on the project definition and allocation of the team for a particular project. The control function is designed for checking the implemented projects. The implementation function serves as a storehouse of information, experiences, evaluation, i.e. the resources needed for any project and various stages of the project lifecycle. The support function is mostly a sharing of software products and databases that are used within the project portfolio management (Doležal et al, 2007).

The advantages of the project office include: narrow specialization for the individual projects, pooling of resources necessary for its management and use of highly skilled project management. It can be less hierarchical for the individual projects, usually it is flat, which means that one to two hierarchical stages are created, and it is strictly subject to individual projects. It is assumed a high success rate for individual projects. Disadvantages can include its considerable independence that may arise as towards the director (owner) of the company so as towards its other permanent structures (other permanent departments in an organization).

The PMO manage the portfolio of projects and provides a framework (standard methodology) for the sustainable management of projects in accordance with corporate objectives and strategies. PMO is a centralized, coordinating authority within the organization (or project) (Řeháček, 2009). Project managers are responsible for the organization within project. It is necessary to clearly define scope, activities and responsibilities of this PMO. The benefits may include the improvement in management of projects and their scope and improving skills and knowledge of PM through training and mentoring, coherence and consistency in the implementation of the project. According to the PMI (2012), the PMO helps to:

- reduce the number of failed projects,
- complete projects within budget,
- increase productivity,
- increase cost savings.

On the basis of an expert assessment of the experienced manager (see fig. 2) are determined 5 main groups of competencies – professional, general, managerial, language and PC competencies (Bazsová, 2015a). These are also valid in the PMO structure:

- Professional
- General
- Managerial
- Language
- PC

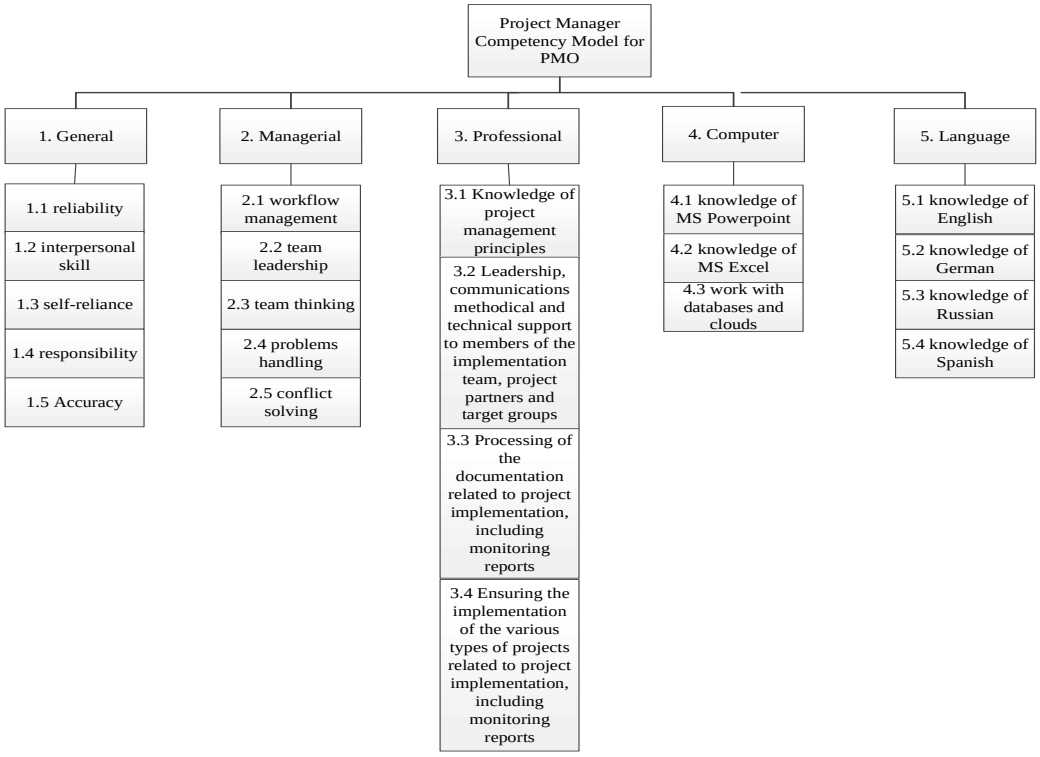

Fig 2. Competences of the project managers (Bazsová, 2015a, modified)

The research question and research design

Adaptation of organizational structures to a condition of competitiveness and innovation needs qualitatively new attitudes towards employee position and work positions. The aim of this paper is to quantitatively evaluate the usefulness of what the preference in the use of both structures from the perspective of experts who act as lecturers, as well as project managers in companies. A group of experts from the Czech Republic were interviewed. They chose criteria (1-8) for evaluating organizational structures. They determined, which of these structures is suitable for a small manufacturing organization (to 20 employees), and then discussed the advantages and disadvantages. There are many aspects which influence the structure design - decentralization, formalization, hierarchical levels, departmentalization, communication among the project team members, etc. (Bazsová, Křížová and Řeháček, 2015b). Based on the experience of project teams of consultants were the most important aspects of assessing these kinds of organizational structures, the eight basic criteria:

1. Expenses of the department
2. The project effectivity and effectiveness
3. Interconnections with other departments
4. Interconnections with costumers
5. Level of formalization
6. Degree of decentralization
7. Degree of hierarchy
8. Competencies

Results

Results opted all the criteria scores on a scale from 1-100%. Experts created results and comment aspects of both structures. Expenses can be measured by personnel costs associated with the existence

of jobs on the line and participation in the project. PMO is a specialized unit for which the organization must train most of their workers and cannot be bought through an advertisement in contrast to the matrix structure. The implications of this are that the costs of establishing a PMO are considerably higher. (see tab. 1). The project effectivity is related to its completion date. The speed of projects with a PMO is faster, as in matrix organizations (without a PMO) conflicts regarding the workload of personnel, and financial and technical resources must constantly be resolved. The interconnections can be difficult measured. The advantage of a PMO, where the competencies are clearly given, is the ability it provides to influence the transition points between the workplace and its processes, e.g. purchasing and implementation, which is the most common source of disputes. In a matrix organization the project manager provides communication between workers involved in the project. A PMO permits communication between processes and workplaces, and sometimes between specialists in the organization. Interconnections with customers solve communication project manager who is responsible for the project and its progress, including compliance parameters. Therefore, in practice it denotes the so-called. Customer Care or Customer Representative. Level of formalization – A PMO makes the description of an operation easier, assuming that a typical matrix organization is already operating. In the matrix organization the rules for project management, i.e. competence, communication, compensation, workload, risk, motivation etc. have already been established. Degree of decentralization – A PMO is a center in which strategic decisions are made, including marketing, economic, and future return. This is when a matrix structure is usually instituted at the management level of organization. Although competencies must be clearly formulated, a PMO is still at a higher level of competence in terms of decision-making and risk management priorities.

Table 1: Aspects of structure designing for evaluation

Aspects of structure	Matrix structure	Project management office
Expenses of the department	50	100
The project effectivity (success)	40	80
Interconnections with other departments	60	90
Interconnections with costumers	80	30
Level of formalization	50	80
Degree of decentralization	50	90
Degree of hierarchy	40	40
Competencies	60	80

PMO is a specialized unit for which the organization must train most of their workers and cannot be bought through an advertisement in contrast to the matrix structure. The implications of this are that the costs of establishing a PMO are considerably higher.

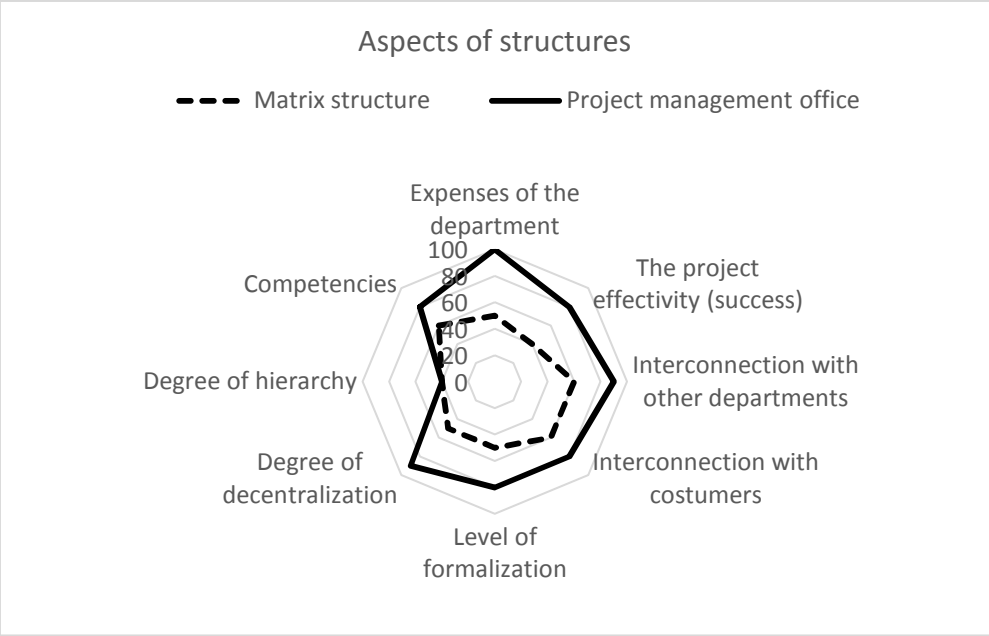

Fig 3. Evaluation of aspects

Conclusion

In the framework of the innovation can organization replace its current structure. It can choose matrix structure or open the project management office. The results from the spider graph shown, that it depends on eight variables – expenses of the department, the project effectivity (success), interconnection with other departments interconnection with costumers, level of formalization, degree of decentralization, degree of hierarchy and competencies. More efficient is the project management office for the organization focused on products (see fig 3).

Abstract

This paper has highlighted the model verification technique used in the study of preserving the e-records event history metadata. The preservation of electronic records event history metadata (PEREHM) model has act as a solution in solving the issues on unavailability of electronic records (e-records) event history metadata model. In ensuring the ten (10) selected elements on the PEREHM Model were viable, the verification process need to be conducted. In the achieving the verification and approval on the PEREHM Model, a Delphi technique was being adopted. This technique has been used in identifying the group of experts that will become the key personnel in verifying the elements of PEREHM Model. After the group of experts has been identified, Face to Face (F2F) interview technique has been used in this study. This was to ensure each of the process of verifying the model elements can reach to maximum result during the verification session. Then, through collective verification statement from the experts, the Atlas ti software has been used in analyzing the findings. This is where the interpretivism technique has been applied. At the end of this paper, it will present the findings from the expert's verification statement. On top of this, the problem identification (Phase 1) and steps in constructing the model (part of Phase 2) of this study have been presented in the previous paper publication (Bunawan at el. 2015; Bunawan & Nordin 2015).

Keywords: Electronic records, preservation, event history metadata, model verification technique

Introduction

In Malaysia, for ensuring the volumes of e-records created in Malaysia Government Agencies (MGA) can National Archives of Malaysia (NAM) has introduced the Electronic Records Management System (ERMS) (Shafie, 2007). On top of that, there were various International Standards Organization (ISO) have governed the process in implementing the ERMS. This is to ensure the management of e-records and its metadata can be preserved properly.

However, the changes of metadata on e-records have continuously increased. This is because the e-records have been transacted to others for accessing and reviewing. Indirectly, it has change the e-records metadata in terms of date, time and access. According to Kettunen & Henttonen (2010), the

sixty four percent (64%) of entire of metadata is about event history. This has shown that the preservation of event history metadata on e-records needs to be attentive.

As being discussed above, this has shown that the issues and challenges in preservation and e-records event history metadata have become the critical issues. A study by Niu (2014) has proves that there were insufficient e-records events metadata that were described by the archives management community. In ensuring this study has provides a factual solution, the discussion with staff from MGA has been conducted. Based on the discussion, the unavailability of e-records event history model has become the main issues that have been addressed by the staffs. As being reported, the development of dedicated model in preserving the e-records event history can become guidelines for staff in MGA. Therefore, this has shown that the objectives of this study are to develop an appropriate model for preserving the e-records event history metadata.

Verification

The verification technique used in this study was adopted from the Verification and Validation technique (V&V). According to Cook & Skinner (2005), *V&V is most effective when the selection of techniques covers the entire life cycle of the model instead of other 75 techniques*. Thus, Harmon & Youngblood (2008) stated that the primary purpose of *V&V is to collect the evidence needed to support an acceptance decision for an intended use*. Therefore, in this study the V&V technique has been used. The Verification technique has been used in verifying the PEREHM Model elements while the validation technique has been apply through a prototype testing.

Technique

In this section, it has focused on the model verification techniques that have been used in the formulated model for this study. Therefore, the figure below has visualized the technique and approach used in this study.

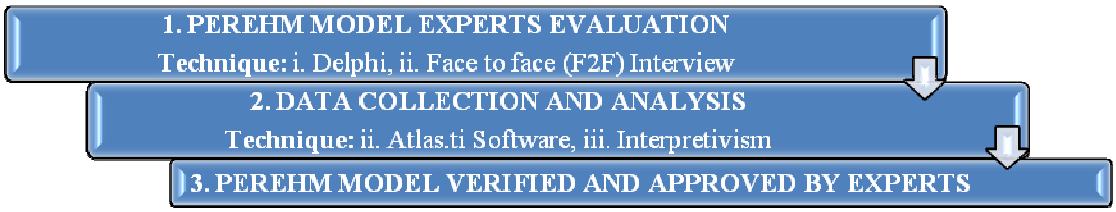

Fig 1. Model Verification Technique

Based on the figure 1 above, there were three (3) process have involved in verifying the PEREHM Model. These include PEREHM Model Experts Evaluation (Process 1), Data Collection and Analysis (Process 2) and PEREHM Model Verified and Approved by Experts (Process 3). In each of these processes, there were several technique needs to be apply.

Delphi Technique

In seeking the approval and verification of the developed model (PEREHM), the type of respondent need to be precisely identified. In this study, the Delphi technique has been used as a mechanism in identifying the qualified respondent. According to Hsu & Sandford (2010) that cited by Konu (2015), One big advantage of the Delphi technique is that it can be used to gather subjective judgments from panelists on issues that have not previously been researched or when there is no documented

information available. Thus, Focht & Ponton (2015) that cited from Gordon (1994), *Delphi technique is that expert consensus is believed to more likely be accurate than an individual forecast*. Therefore, there were eight (8) NAM branches including the headquarters have been identified.

Face to Face (F2F) Interview

As being discussed above, the Delphi technique has been used in identifying the experts. These experts have includes every Directors of NAM state branches. In this study, the verification of experts has been conducted using Face to Face (F2F) interview approach (Grovermann at el. 2015; Requena at el. 2012). According to Gorovaia & Windsperger (2010), *Face-to-face is the richest communication mechanism because it has the capacity for direct experience, multiple information cues, immediate feedback and personal focus.* Therefore, the verification of PEREHM model elements has endured an in-depth F2F discussion with each of the Directors in separate session.

Atlas ti Software and Interpretivism

In analyzing the data collected, this study has used the Atlas ti Software 7.0 Version. According to (Candy, 2006), Atlas ti is an application for the visual qualitative analysis of large bodies of textual, graphical and audio video data. According to Mena (2015) in his Doctoral Dissertation stated that, the *Atlas ti is a computer assisted qualitative data analysis software program that uses a grounded theory approach to code, display, and systematically analyze for thematic patterns across cases*. Greene (1994) has defined interpretivism *is about contextualized meaning*. Nicholls (2009) stated that *phenomenology sits firmly within the philosophy of interpretivism, or hermeneutics (which derives from the Greek word to 'interpret')*. In this study, the interpretivism approach has being mapped to the data collected in producing nodes based on Atlas ti data process result. Through the interpretivism process of data analysis, the creation of nodes becomes precise to be used as concrete evidence in achieving the PEREHM Model viability. Therefore, this has shown that the used of Atlas ti software in this study has completely in analyzing the qualitative data for model verification purposes.

Discussion

Based on the technique driven, the table below has presented the findings on the verification of the PEREHM Model in this study.

Table 1: PEREHM Model Verification Statement

No	Model Verification Based on Ten (10) Selected Variables	
	NAM State	**Verified**
1.	NAM Headquaters	This model must be used for the completeness of e-records reports submission towards preservation purposes.
2.	NAM Kelantan	This model must be used as a tool in capturing e-record transaction activities.
3.	NAM Terengganu	This model must be used as the mechanism for effective e-records process flow.
4.	NAM Pulau Pinang	This model must be used as the completion of e-record metadata process.
5.	NAM Kedah/Perlis	This model must be used for standardization aspect on e-record preservation metadata.
6.	NAM Pahang	This model must be used as an important process in preserving e-record event history metadata.
7.	NAM Perak	This model must be used as a general model for preserving e-record metadata in e-records system.
8.	NAM Johor	This model must be used to structure the event history metadata on the e-records management system.

The table 1 above has visualized the entire statement from the experts that have been completely analyzed using the selected verification technique. This has shown that, in verifying the new proposed model, the selection of technique was important. This was to ensure each of the process in verifying the model elements and its viability towards the issues driven can be fulfilled effectively.

Conclusion

As a conclusion, the verification technique that being used in this study has contributed to the completeness of process in verifying and approving the PEREHM Model elements. The findings have shown that the PEREHM Model can be used as a qualified solution in solving the issues driven. The verified PEREHM Model can also be used as guidelines in managing the e-records. Using the MGA as a sampling of the model development case, this study can become guidelines for producing a new model in other perspective and domain. Thus, as for this study, the validation process of the verified PEREHM Model needs to be completed. Through development of prototype, the process of validation can be completed. The development of prototypes will be explained in the next phase of this study.

Consolidated Group of Taxpayers as the Way of Sustainable Of Economics[1]

Kristina Alekseyevna Bannova, National Research Tomsk Polytechnic University, Tomsk Polytechnic University, 30 Lenin Avenue, Tomsk, 634050, Russia, bannovaka@yandex.ru

Abstract

At the last five years rapid development of world economics is related to use raw materials key world power. As a result possible of raw material export has becomes complementary incentive economic development of developing country. The main raw materials became ore, timber, natural gas and oil. The last one is the crucial product for economic development of many oil-producing country. The striking specimen that country is Organization of Petroleum Exporting Countries (OPEC) and Russia. Consequently, the level of mining operation and export of raw materials has been ascertained sudden change to economic development from at 2008 to 2014 years.

Keywords: OPEC, major of raw company, tax payment, consolidated group of taxpayers, state.

Introduction

In 2014 an abrupt decreasing of oil price was observed. The decreasing influenced on economic situation at the OPEC and Russia. Extensive method of development of the oil branch in the countries leads to increasing of the mining operation volume. As a result, the satiety on the raw material market was observed. Thus, Russia needs to look for the optimal correlation between the volume output and price, for support their economics, which in many respects ascertained the level tax payment.

Anticipate instability on the world primary (including the oil) market, the Russian taxing authority in 2012 was introduced a new system «Consolidated group of taxpayers» (CGT). Similar system is much used in international practice. It was intended for stimulated grown of company by way of replacement of fixed assets. As the result of using the CGT-system the cost saving of product, the improvement quality of products are expected. All of that led to development of company. The practice distinctive feature of using the CGT in Russian is the support the major of raw company (Gazprom, Rosneft, Lukoil, Transneft and others). This support is aimed to alleviating the financial commitment of largest company afore the state for certain functioning on the world market. Finally it is expected the increasing of tax payments on account of stable position of the company in the world. Thus, it can be conditionally divided two way for supported stability of economics by the OPEC and Russia: to find out the optimal correlation mining operation and price for oil and used the system of CGT correspondingly. The work is devoted to analyses of effectiveness of the ways.

To analyze of economic situation in the OPEC and Russia we choose the period from 2012 to 2015 year. The period noticeable for the fact that first half is describe the top price for oil, while the second - low price. In that condition it is succeed to make the analysis of tax payment dynamic and determinate of effectiveness way stability of economics.
To make the analysis of way stability of economics, which used by the OPEC. For the analyze choose the country of top five: Saudi Arabia, Iran, Iraq, Kuwait and Venezuela. At figure 1 chart of tax payments is presented from budget of state, in according to the official data.

[1] This research was financially supported by Russian Foundation for Basic Research (RFBR) in the frame of the project for scientific studies (Mathematical modeling of the formation activities consolidated group of taxpayers to harmonize the interests of the state and taxpayers), project No. 16-36-00184.

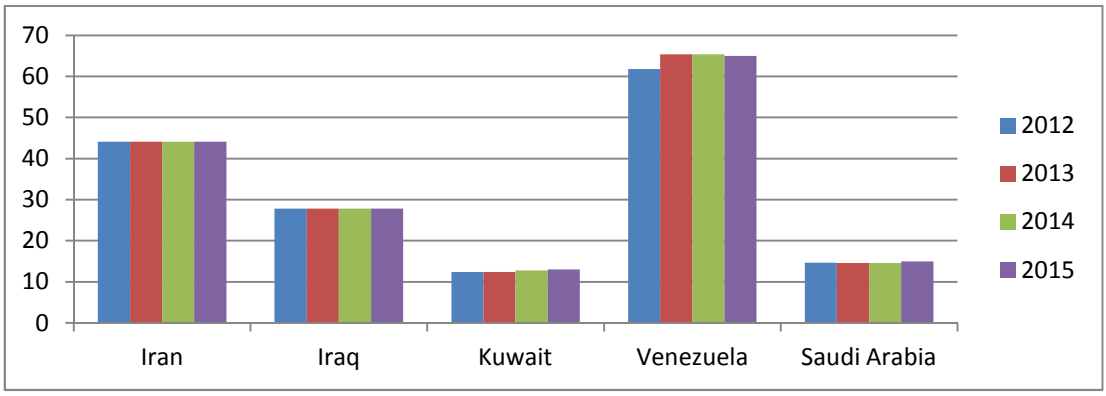

Fig.1 – The time dependence of tax payments.

It is shown that dynamic of oil market is not render material effect to the tax payments. That stability of tax payments can be the explained in the following way. Obviously, that the main correlation index of economic situation for OPEC is export and Gross Domestic Product (GDP). Consequently, the quantitative research for assessment of stability the tax payments, should carried out based on three parameters: export, CDP and tax payments. For assessment correlation that parameters calculate the correlation coefficient:

$$r_{XY} = \left[\sum_{i=1}^{n} \left(X - \langle X \rangle \right)^2 \sum_{i=1}^{n} \left(Y - \langle Y \rangle \right)^2 \right]^{-1/2} \sum_{i=1}^{n} \left(X - \langle X \rangle \right) \left(Y - \langle Y \rangle \right), \qquad (1)$$

were n – number of years.

Table 1

The data table for calculation

	2012	**2013**	**2014**	**2015**
Export				
Saudi Arabia	388.4	377.0	359.4	395.1
Iran	67.0	93.0	95.7	97.4
Iraq	97.2	89.8	94.4	99.7
Kuwait	121.0	112.7	109.9	125
Venezuela	97.3,	88.8	83.2	96.5
Gross Domestic Product (further GDP)				
Saudi Arabia	740.5	927.8	1616.0	1740.0
Iran	997.4	987.1	1284.0	1296.1
Iraq	130.6	221.8	232.2	243.1
Kuwait	165.9	165.8	283.9	294.3
Venezuela	402.1	407.4,	545.7	551.2

The result of calculation present on figure 2.

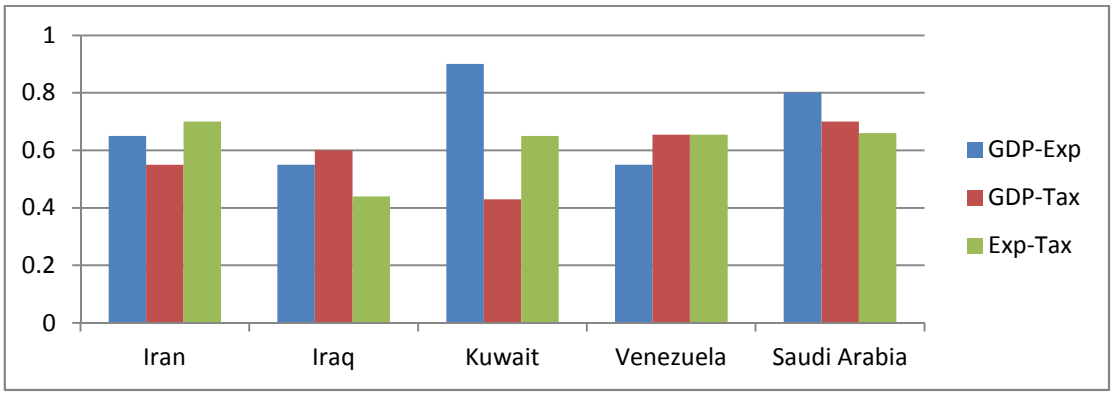

Fig. 2 – Correlation coefficient between export, GDP and tax payments for OPEC

It is shown, close coupling between the parameters. That declarative of optimal policy for the OPEC, which admit to correct of tax payments by increasing of export during the unstable situation on oil market.

Perform the similar analyses for Russia. At figure 3 presented the time dependence of tax payments for Russia.

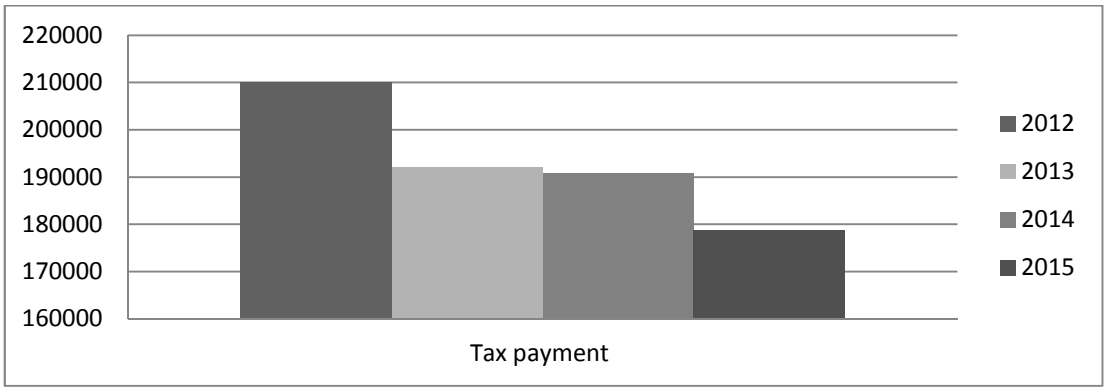

Fig 3 – The time dependence of tax payments (in thousand rub.)

It is shown, that tax payments in Russia at 2012 was decreased. In part of decrease can be due to the fact that in 2012 year system of CGT was introduced. The system was designed to support the main raw material company by the side of state. Obviously, as the result of support one can expected hardening that company on the world market and as consequence increased tax payments in treasury of state. To analyze the activity of the companies we performed similar calculation by the OPEC. The results of the calculation are presented on figure 4.

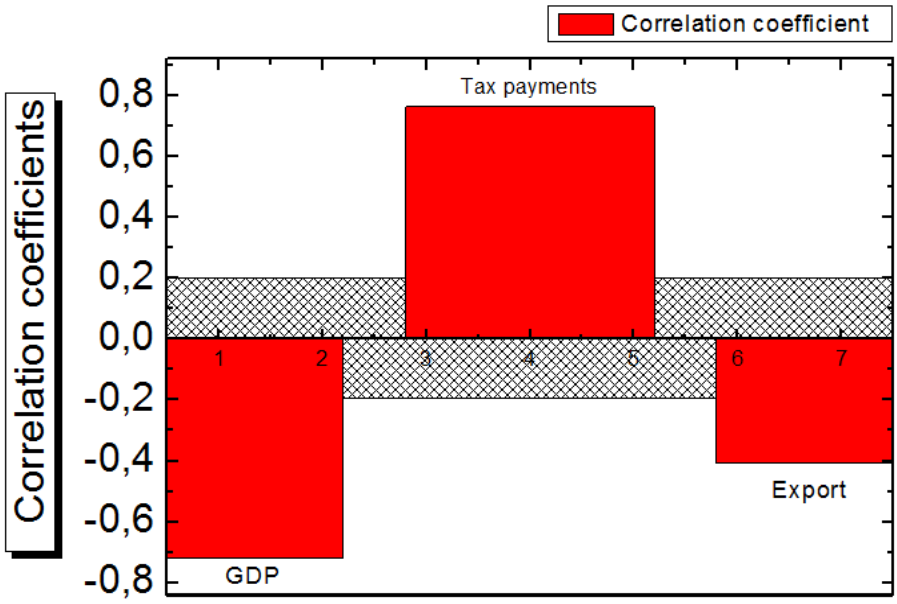

Fig 4 – Correlation coefficient between export, GDP and tax payments for Russia

It is shown the correlation dependence between falling the tax payments and grown GDP and export.

The consider contradiction can be associated with the falling of course ruble. To make the assessment conditional value equal multiplication of course dollar and the level of oil production (the level of dollar revenue). Obviously, this value characteristics the corporate income. The results of calculation are presented on figure 4.

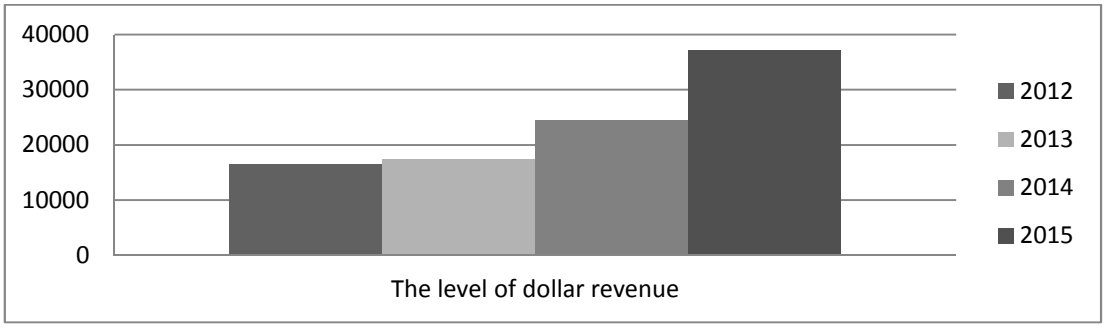

Fig 4 – The level of dollar revenue

One can see that each years was increased the dollar revenue. Obviously that this increased should increase the tax payments. However, as previously discussed look at fig.3 the level of tax payment is not only increased, but also decreased. About that leading similar time dependence of revenues, which is shown in figure.5.

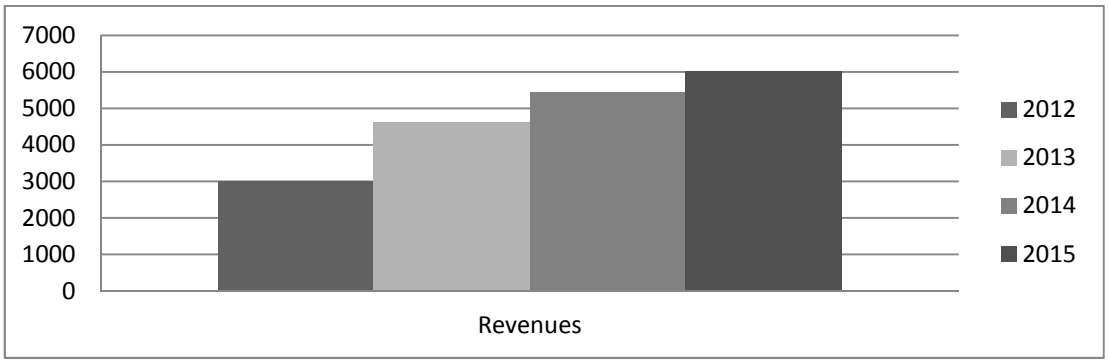

Fig 5 – The level of revenues

Thus, our investigation shows the gap between profit tax to be paid by the company that was estimated on the basis of their financial activity indicators, and actual profit tax paid in budget; estimated profit tax is significantly higher than the actual one. Russian oil companies after forming of CGT began seriously to develop: was proportionally increased cash flow, oil production, exports. However, this has not led to the desired results: the volume of tax proceedings significantly reduced. That leads to destabilization of the economic situation in Russia. Therefore, we can conclude that way of the economic situation stabilization due to the export of oil resources applied by OPEC, is optimal. A Russian model CGT needs to serious revision.

Conclusion

In our research we analyzed the economic situation in 2012-2015. As part of this analysis, we discussed the effectiveness of two ways of the economic situation stabilization by OPEC countries and Russia. The way used by the OPEC is to increase oil production to adjust tax proceedings. The way applied by the Russia is to use the system of the consolidated groups of taxpayers. We evaluated the effectiveness of both ways by means of the correlation coefficient. Indicators in regression with significant correlation are the follows: exports volume, GDP and the level of profit tax paid by oil companies. A key factor in this correlation was the tax proceedings. We revealed that the profit tax proceedings level in OPEC countries remained unchanged regardless of decline in oil prices. In Russia – on the contrary – profit tax proceedings decreased despite the growth of GDP and exports volume. Thus, in our point view the Russian CGT system is needed to modify.

Abstract

This paper highlights the international forms of cooperation in research and development for medium enterprises and it is based on the example of an enterprise from Germany.Medium enterprises face more and more difficulties to state a self-maintained position in the context of commercial competition since the modern production techniques, the high-tech large-scale enterprises often favored and the competition growing due to largely saturated markets. When the autonomous growth ceases because of the financial reasons, the only possibility is to merge with other enterprises from research and development field.This paper is based on a literature review from "international cooperation forms" field and on the study of an enterprise from Germany.The aim of this paper is to present different methods of international cooperation and to derive their optimal shape based on a study of an enterprise. To realize this objective, the authors conducted an analysis of an enterprise from electronic industry field in the period of PhD studies.

Keywords: supply chain management, risk management, outsourcing and insourcing

JEL Classification: G10 General

Introduction

The aim of this paper is to highlight the reasons and advantages of cooperation in the international context using the study on an enterprise within R & D cooperation from Germany.

The opening of global market offers to companies expansive opportunities for activities[1]. The increasing competition, intensive trade and increasing international mobility on internal market, are leading to an enhanced pressure. This pressure is forcing local enterprises to adapt themselves.

The increasing constraints for internationalization of various companies make it clear that the nature and extent of their internationalization activities are afflicted with very large gaps.

By analyzing the companies' current market situation we may conclude that the internationalization of companies is well advanced.

In Germany, medium enterprises are already about 30% in some form internationally active, being heavily distinguished by the outnumbered large enterprises[2].

Literature review

Cooperation, from the Latin “cooperatio" (cooperation, collaboration), is the interaction between two or more individuals, persons or systems, particularly on economic or political basis. This work considers begins from cooperation between companies; therefore the main focus lies on business cooperation. In most cases it is about the cooperation of two or more companies for increasing their common competitiveness[3]. The literature addresses two main criteria[4]:

- Maintaining the economic and legal independence of enterprises
- Coordination and implementation of joint activities

For the implementation, the participants of such network cooperation are using shared resources and expertise. The alternative is to ensure the same performance through own forces by building up resources or by acquisition on the free market. In this respect, the business cooperation can be considered as an alternative form of organization, which occupies an intermediate position between the market and hierarchy, meaning it stands between contractual regulated and over hierarchy controlled cooperation[5].

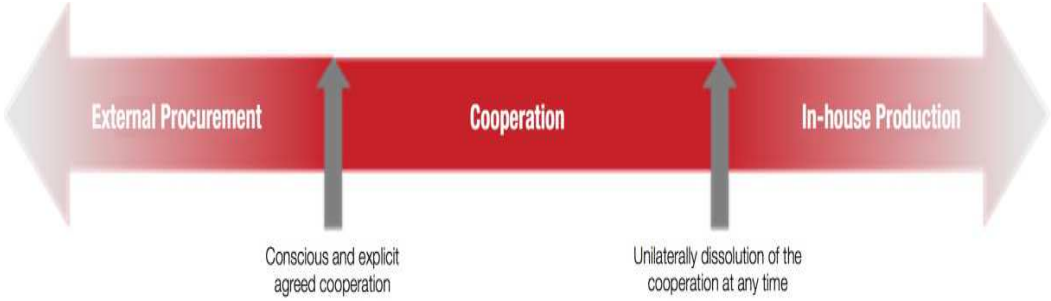

Fig. 1 The continuously cooperation in market-hierarchy

Source: Becker, 2005

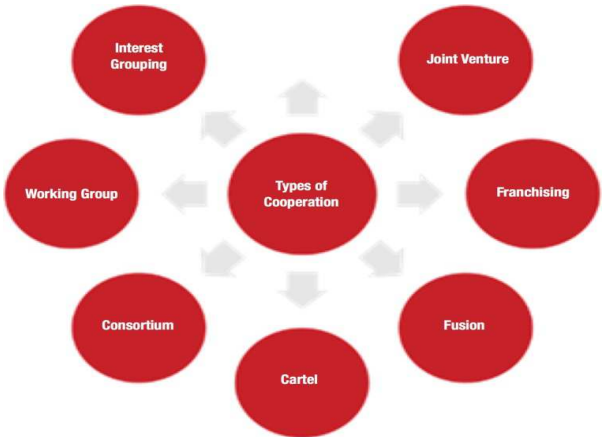

Fig. 2 Types of cooperation

Source: made by authors

The figure 2 presents the different types of cooperation.
Each type of cooperation is detailed in the table below:

Table 1: Types of cooperation

Types of cooperation	
Social group/Interest group: A social group is composed of few or more enterprises which set the goal of enforcing common interests. This form of cooperation is usually controlled by a simple contract and is headed by a chairman employed for this purpose. A classic example is the employer representative[6].	**Strategic Alliance:** Strategic alliances, often temporary interrelations (often horizontal) between companies in the same industry whose action relates to a specific business segment. In this form of cooperation it is about pooling resources to achieve a competitive advantage over competitors.
Working group: Working group is especially common in the construction field and serve more companies in a merger for the joint implementation of a project, for example, a major construction project. This form of cooperation is limited in time and usually occurs as a company constituted under Civil law.	**Joint Venture**: The cooperation model of Joint Venture represents the founding of a legally independent company by two or more legally independent enterprises, wherein the reason for the collaboration is to accomplish certain tasks jointly. Joint ventures are usually unlimited and in any direction, i.e. horizontally, diagonally or vertically possible[7]. The reasons for founding a joint venture, may be the association of capacities, pooling of resources or avoiding duplication of investments.
Foreign Trade Cooperation Foreign trade cooperation could take the form of export or import cooperation. For export cooperation or export association single or multiple delivery tasks are divided among the cooperation's partners. Import or buying cooperatives achieve financial benefits by pooling purchases at national and international procurement markets[8].	**Franchising** Franchising is a collaboration between legally independent franchisors and franchisees, whereby the franchisor is responsible for the tasks of planning, implementation and control of a previously successful operation type. The franchisee, in turn, receives the license, of this concept including the services and products to be distributed according to the existing concept[9].
Cartels Generally, cartels are characterized of existing based on a contract which is suitable to influence the market conditions by restricting competition, whereas legally ineffective according to restriction of competition law[10]. The companies are connected horizontally and remain legally independent.	**Fusion:** The merger represents the most extreme form of cooperation; as independent companies legally merges into one company under one name. Often, smaller companies are this way taken over by stronger partners.

Source: made by authors

Research Methodology

To reach this objective, the authors had conducted some interviews with the two managing directors. The interviews are used to identify the reasons for business cooperation and to derive the future type of cooperation.

For giving a better statement of an appropriate international cooperation form, it was made a detailed business analysis on the enterprise studied and were summarized the results in a core competency matrix.

Based on these results and the interviews conducted, the reasons for the cooperation between companies inside of the example company was worked out on the basis of theoretical fundamentals and possible cooperation ways in the field of R & D.

These results lead to the recommendation of the possible business cooperation.

Research results for international forms of cooperation on the example of the enterprise studied

For industrial companies, research and development[11] is a popular area for cooperation within the strategic alliances cooperation type and therefore an indispensable part of daily work.

To withstand the mentioned pressure of competition and innovation, small and medium-sized enterprises are often forced to close development collaborations.

Attributes of such cooperation initiatives are that the partners participate voluntarily to the cooperation, follow common interests and register economical profits from that specific project[12].

The collaboration can, but must not, be restricted to a certain time frame or achievement of specific targets.

While taking into account common targets, subtasks of the cooperation are being completed and jointly worked out. The cooperation is legally underpinned by tacit or contractual agreements[13].

The analyses undertaken revealed that the grounds for entering cooperation in the R & D area may be completely different. The most important considered targets and opportunities for the Sample

However, the objectives are not clearly separable, but often interconnected and are mutually reinforcing each other.

Table 2. Grounds for R & D collaborations

Grounds	Targets and Opportunities
Complementarity	Companies are entering a cooperation if own resources are not enough to conduct a sought R&D project. Therefore, resources may be used additive or complementary. At an additive bundling it is about a project which is simply too large and more capacities are needed; whereas, conversely, in the complementary method it is about connecting not existing resources with its own. Thus, an effective implementation of a project can be better realized[14]. The pooling of resources continues to bring scale economies, which may lead to a reduction of variable costs. This advantage is particularly important for small-sized companies. They can implement many projects through the pooling of resources with partners[15].

Cost reduction	Companies are urged by the increasing time and cost pressure to a steady reduction of costs. Through resources, procurement, installation and usage of equipment, development and further production, costs are rising in any phase of the innovation process. Basically, cost savings can be realized through economies of scale, economies of scope or learning curve effects, respectively knowledge building. Costly redundancies can be avoided and business processes run more efficiently by integrating information and communication technologies. In addition, double investments are thus avoided and the development costs shared within the cooperation[16].
Time savings	Through cooperation, development initiatives have more human, technical and financial resources and can thus be carried out more quickly and efficiently[17]. This is a necessary consequence which must be drawn from the trend towards more rapid innovation and technology cycles and shorter product life cycles, while increasing product complexity[18]. The resulted shortened duration of the project reached by pooling of resources are also reducing the binding of cost-intensive resources[19].
Knowledge gain	The company's internal know-how is one of the most important resources to secure competitive advantage. Within an efficient cooperation, know-how can be exchanged controlled, whereby both parties achieve best results. In this respect collaboration is an opportunity to acquire new knowledge. This is done by the targeted knowledge transfer, yet also by generating expertise. Know-how transfer means that previously existing knowledge of a company is incorporated in the cooperation and the partners acquires this new knowledge. Similarly, through the cooperation, partners can benefit from the so-called Innovation Learning (Best Practice)[20]. If the associate members are liaising knowledge and experience to new ideas than Innovation Learning takes place[21]. The gain of knowledge in turn leads to cost and time savings and can bring other positive effects, such as quality improvements.
Capacity supplement	A capacity supplement follows a similar pattern as the economies of scope. It means pooling of resources through which larger projects can be realized. Those might be among others, financial capacities or for example, output capacities, equipment or personnel.
Risk reduction	Each R & D project is associated with risk factors. If the costs are shooting up, the developed “passes over the market” or feasibility problems appear, development projects can turn into million graves, which cause the company long term negative consequences. To reduce the threat, the allocation of such risks on several network partners is an effective measure, as at the occurrence of such risk factors the entire cooperation spreads the cost or have enough resources are available to improve or save the project[22]. From a risk management perspective a higher risk means also a higher return, which in case of a partner would be cut in half.

Market access facilitation	Market entry and mobility barriers can generally prevent the entry into a new market. Increased capital investment or gain of know-how and technology can overcome these barriers. The missing resources may be provided by cooperation partners and the access to new markets from home or abroad is obtained through business connections. Especially abroad the resident partner can help to overcome commercial barriers. Through partners also knowledge of the new market can more easily be acquired and making the chances of success best improved[23]. These new contacts can be strengthened by further successful collaborations which buildup a healthy corporate network[24].

Source: made by authors

Within the first step, the results of the study answered the question about the grounds for a business cooperation of the sample company.

Based on the range of occupations, the sample company is more of a specialist - and not a complete range products provider. With its division as controller, image processing and computer systems, the sample company is more application-oriented and less product-oriented.

Since the company is not a technology leader, the sample company uses new technologies in electronics, respectively in the field of microelectronics and image processing for the research and development of the own products.

In order to make statements about the core competencies of the sample company, was developed a core competency matrix.

The results of the conducted interviews and the business analysis are represented below:

Table 3. Core competence matrix

Area of competence	Critical skills	Is-situation	2015
1. Product/Project specific competencies	- technological workout, further development and manufacture of existing product solution	+	
	- development and manufacture of new product solutions based on existing or new technologies	+	+
	- maintaining and further development of the technological level	+/0	
2. Market specific skills	- reccognising customer's new needs and development and execute them effectively		
	existing markets	0	+++
	new markets	0/-	
3. Functional abilities	- delivering customer specific top solutions	+	
3.1 Production processes/Departments	- push through high prices	-	
- Development	- offering complete product range	-	
- Distribution	- offering good services	+	
- Technical contract development	- new customer acquistion	-	
- Purchasing and Manufacturing	- offering complete solutions	0	
3.2 Supporting Processes	- delivering system solution	0	++
- Technology	- efficiently manufacturing	0/-	
- Human Ressources	- cost efficiently procuring	0/-	
- Infrastructure (IT, QM, FI)	- using, binding and recruiting highly skilled employees	+/0	
	- fast pay-back from R&D Investments	-	
	- low quality management costs	0	
	- procure new financial resources	-	
4. Cross key topics	- strategical marketing	+/0	
	- product management / V-products	0	
	- first class cost management	-	+++
	- management and control of heterogeneous businesses	-	
	- technological/commercial Project management	0	

Capacity + high developed / 0 medium developed / - low developed

+++ very high ++ high + less high

Source: made by authors

Looking at the picture more closely, it can be seen that the sample company is aligned technically-technologically and can provide customized solutions in the mid and high-end segment. However, the skills for R&D are not sufficiently pronounced to generate here a great added value for the sample enterprise. This problem is reflected, among other things, by the accepted and sells research contracts without knowing how long will take the development of the appropriate solution. The consequence therefore is that are needed more days for the development, which cannot be charged. This results, in

a great financial loss for the sample company, which, in most cases, cannot be retrieved on the sale of the developed product.

From this, can be derived the following strategies for research and development:

Table 4. Objectives for the research and development

Goal / Strategy	Example
Cost reduction	Develop cost-optimized product solutions for defined applications or customers
Quality improvement	Develop quality-oriented products for defined applications or customers
System solutions	Deliver system-solutions and not components or modules

Source: made by authors

Because the sample company of medium-sized companies is too small, for ensuring a cost-optimized R & D business it has to enter into the cooperation area. This way, synergies can be reached which creates added value not only for the Sample Company but are also interesting for the cooperation's partners. Because only this way can the cooperation's partners withstand the cost, innovation and market competency pressure[25]. Through the one international cooperation form new funding can also be obtained, which initially takes the cost pressures of the new research and development projects. The international development cooperation have also the advantage that thereby new distribution channels can be developed with which new markets are opening up to.

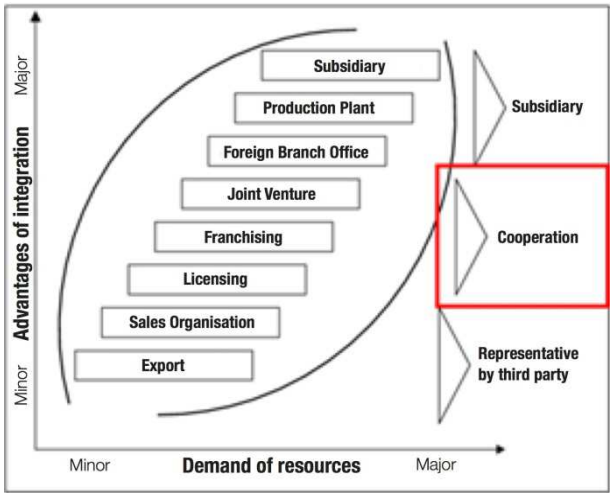

Fig.3 Market Entry forms

Source: Gabler, 2015[26]

Another reason for entering into collaborations is that incentives are not made as prior to the extent of the country. Thus, the Sample Company is formally compelled as a medium-sized company to cooperation. Incentives are critical, especially since the projects are often lost and the actual research and development costs are not covered and completely supported by the Sample Company.
The company tried to be successful with various cooperation types. Therefore, company has strategic partnerships in the areas of customer and supplier relationship that were used for entering new markets and increasing sales. In addition, this type of co-operation is used to strengthen customer relationships and to obtain access to new contacts and trade fairs.

In the past, the enterprise studied has cooperate with another company, which is commercially distribution-oriented. However, cooperation lasted only one year and was dissolved by the partner,

due to commercial reasons. The aim of that company was to learn about the Sample Company out from the cooperation and buy it cheaper afterwards. Finally, the Sample Company had a whole range of incentive projects, which have not brought the desired long-term success.

Just this past cooperation example shows that the Sample Company has always had a weak partner and the last one was focusing only on its own advantage.

Considering the problems in the past, which have occurred in different collaborations of the Sample Company, it becomes quickly clear that the company must take a different approach to reach long-term success in international markets. A strategic alliance in the field of research and development (R & D cooperation) may be for the Sample Company a good option in order to step abroad and continuing to be international. Through this type of cooperation, it becomes possible for the Sample Company to remain legally independent and still having the opportunity to carry out collectively certain tasks, especially in the area of research and development. In this context, it is of secondary importance whether the strategic alliance in the field of research and development, is unlimited or made only for a specific research project.

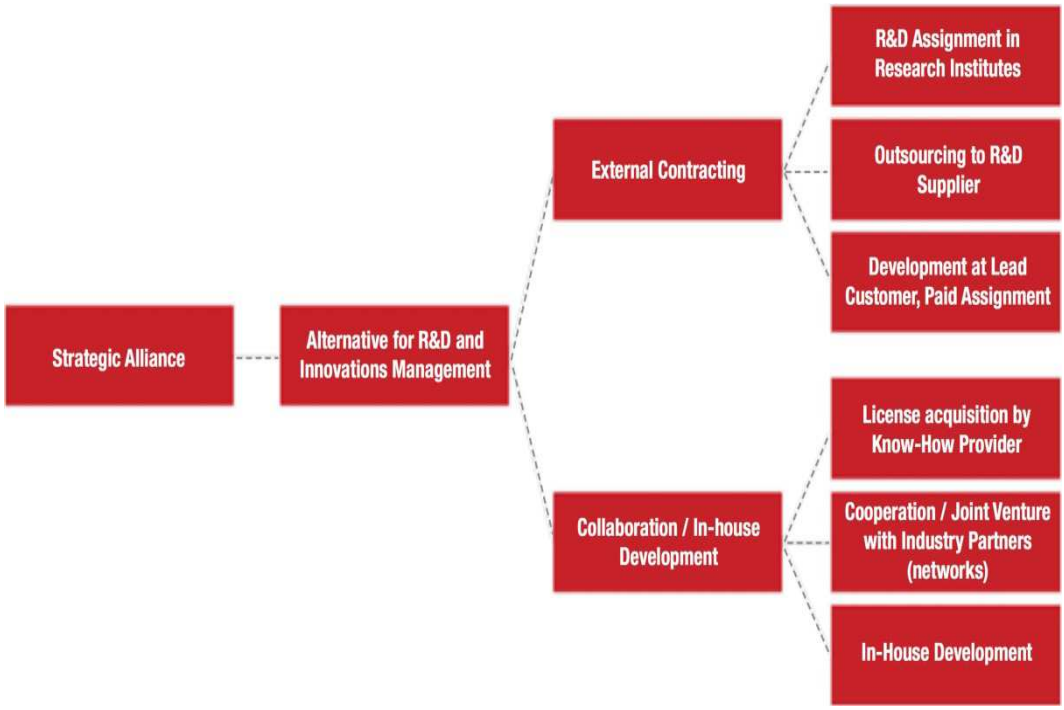

Fig.4 Example of cooperation types in the enterprise studied

Source: made by authors

Conclusion

The results of the research undertaken showed that regardless of size and industry cooperation, in research and development companies is included within the daily operations. While earlier research was done by individual scientists with pencil and paper and carried out in inexpensive laboratory equipment, nowadays, it is necessary to cope with the immense costs of research that can only be worn by several companies together.

Today we speak about an European economy, where companies operate mainly international. The interaction between national and collaborative funding of the EU Member States can lay the foundations for a European dimension of cooperation in research and development.

Cooperation is becoming more complex, dynamic and multi-faceted. The cooperative abilities of both large and small-sized companies have become the main criteria for a long-term success. This is accompanied by process and IT standards, which are the basis for an effective collaboration between several enterprises. Reports and comments from all research-intensive sectors show that it needs a greater cooperation. Classical approaches of "competitive markets" are reconsidered and increasingly efforts are sought in the context of cooperation and competition in complex "co-opetition" networks. A prevailing example in literature and the news is the automotive industry.

Equally, similar surveys of companies in various industries are documenting that cooperation are carried out in all areas and gain even more importance in the future development. By standardizing and optimizing cooperation from process perspective by the aid of modern communication and organization tools, efficiency and effectiveness can be increased, thus leading on ensuring company's success for the cooperation partners, and on the advancement of national and international science.

Research results showed that the enterprise studied has illustrated the opportunities given by a research and development cooperation. The success is primarily given by the grounds of this form of cooperation, through which, medium-sized companies competitively remain. R & D cooperation can thus serve as a successful alternative collaboration for remaining successfully in the market. For the Sample Company, an R & D cooperation is a good way of growing internationally. For this reason it is recommended to implement R & D cooperation in the context of a market entry strategy as of the Sample Company to permanently be successful on the international market.

Abstract

Labeling Halal foods must consider the difficulty to achieve the business goal by individual organizations because relationships between supply chain actors in Halal foods is affected by the power collaboration an entity to influence another entity to ensure quality assurance system. The purpose of this paper develops a conceptual framework of supply chain Halal foods with considering the power collaboration between supply chain actors from a literature review. The framework is conducted using the SCOR model as modeling tool to investigate the power collaborations between suppliers, manufacturers, distributors and buyers in producing Halal foods. Finding of this study provides a conceptual framework of supply chain Halal foods to develop effective collaborations within the partnerships. Further research suggests conducting other factors that can affect the supply chain Halal foods involving regulations for each region that implement the policy of Halal foods in greater detail.

Keywords: Halal foods, SCOR model, supply chain, power collaboration.

Introduction

Halal foods required to adopt the supply chain strategy from upstream to downstream to provide the best service in term of quality assurance system to the market. In this way, the buyer has sufficient confidence in consuming Halal foods through basis of trust in the Halal certification as shown on the consumer product or outlet such as a meat shop or restaurant. This certification provides assurance that the product involving the source and facility has been verified by an independent Islamic Certification Authority to be compliant with Shariah laws (Bonne and Verbeke, 2007). Nevertheless, to ensure in labeling Halal foods, the individual organizations must consider the collaboration between supply chain actors that is affected by the power an entity to influence another entity in producing Halal foods. Therefore, Katunzi (2011) revealed that for successful implementation of SCM practice, it depends on the need for breaking down barriers not only between internal issue and business processes, but also across companies within the whole supply chain.

Some researches noted the concept of power collaboration is defined as the ability of one entity to influence the strategies of another entity in order to achieve the effective workings in the relationships and success to gain the competitive advantage (Belaya et al, 2008; Ke and Kee Wei, 2008). Moreover, firms developed the collaborations between others supply chain actors in order to achieve efficiencies and competitive advantage in greater benefits for companies (Quesada et al, 2012). Indeed, supply chain practice gained considerable importance because it is difficult to achieve the business goal by individual organizations. Nevertheless, it is easily achieved through collaboration between supply chain actors (Koçoglu et al, 2011).

The aim of this study develops a conceptual framework of supply chain Halal foods with considering the power collaboration between supply chain actors from a literature review. The framework more is conducted using the SCOR model as modeling tool because this model able to manage the supply chain strategy that provides benefits for business process as networking that associated with suppliers, manufacturers, distributors and customers (Fitra el al, 2013). The paper reviewed several publications available was mainly conducted through online databases in order to search related articles about Halal foods, supply chain practice and power collaboration. Taking into account the limitations below, the total number of 50 papers was found in this study. In addition, the research considers only journal paper and other references published in the period 2000 to 2015. Obviously, this study is expected to be able to contribute in developing the conceptual framework of supply chain Halal foods based on power collaboration between actors of the supply chain.

Supply Chain Strategy

Supply Chain Operations Reference (SCOR) model is able to utilize the process reference in the supply chain strategy. Moreover, this approach is used as a set of key performance indicators (Singh et al, 2013), a modeling tool (Bolstorff, 2011), a benchmarking tool (Ambe and Africa, 2014). This method also is used to investigate the collaborations between suppliers, manufacturers and customers (Wang et al, 2010). In addition, for reengineering business process using SCOR model, it is done based on the stages that have been standardized involving *plan, make, source, deliver and return*.

SCOR model is a methodology that can facilitate the blending of business objective, strategy, process and technology in the supply chain (Gulledge et al, 2001). In addition, the SCOR model develops the business processes of an interconnected flow material between business networking as a modeling tool (Verdouw et al, 2010). The advantage of this model, users can design business chain and to develop strategies and improve on technology within a business process. Moreover, SCOR model defines the process into several levels (Cheng et al, 2009). Moreover, SCOR model is also a tool for benchmarking and configuring the strategy of the supply chain which emphasizes there are several measurements in supply chain management (Drzymalski et al, 2006). This measurement is a tool for benchmarking between companies and competitors (Yakovieva et al, 2009). Best practice is a way to improve and configure a set of supply chain processes. Improvement can be done through automation, technology, special skill applied in the process and unique method for distributing. Several software's provide modules to do best practice based on process at each level.

Power Collaboration

The concept the power collaboration adopted based on the marketing and competitive strategy concepts which it is frame thinking of five force competitive models by Michael Porter at 1980. Pother's five frameworks are a model to configure industry and its competitor in order to identify entity and interactions. There are five frameworks, basic of the competitive strategy model involving industry competitors, threat of substitute products, bargaining power of suppliers, bargaining power of buyers and threat new entrants. This model provides a simple perspective for assessing and analyzing the competitive strength and position of a corporation or business organization (Rachapila and Jansirisak, 2013). Some researches success to leverage Five Forces of Competitive Model to develop other models of competitive model (Jaradat et al, 2013; Grundy, 2013; Renko et al, 2011).

The collaboration between supply chain actors give impacts on competitive strategy. Lemke et al, (2003) studied at four engineering companies in Germany. They revealed manufacturer required to develop effective collaboration with other partnerships in order to provide the best service to the customer. Moreover, Mohanty and Gahan (2012) conducted in the Indian manufacturing sector. They found the role of the manufacturing shows that buyers and supplier becomes more crucial in building collaboration for long lasting partnership with supply chain partners. Thus, it is necessary to conduct the collaboration manufacture in term of competitive strategy in business process. Moreover, there are many partnerships to support firm or manufacturer to run the business process involving

suppliers, distributor and customer. Thus, the collaboration among supply chain actors is expected to determine the power position.

Previous studies on supply chain strategy that support power collaboration including the power of suppler, power of manufacture, power of distributor and power of buyer. Then, it also can be seen in Table 1. There is the power of the supplier to affect the manufacturer in order to push the product based on the supplier's forecasting. It means the supplier holds substantial power to affect company's margin and volume (Braak et al, 2013). According to Gadde and Snehota (2000), this condition occurs because there are very few suppliers of a particular product so it causes there are no substitutes of the product. Furthermore, the product is extremely important to the manufacture because they cannot run the production without product from the supplier. Echtelt et al (2008) evaluated long term and short term relationship with the supplier. It is helpful in understanding the certain collaborations are effective.

Table 1: Power collaboartion in the previous literature

Power Collaboration	Prominent Authors	Dimension and perspective on power
Supplier	Al-Abdallah et al (2014)	Cost, quality, flexibility, delivery, and on time product launch.
	Krause et al (2007)	Supplier development, commitment, social capital accumulation and buying performance.
	Echtelt et al (2008)	Long-term strategic processes and short-term operational processes.
Manufacturer	Mukhtar and Shaharoun (2002)	The impact and position of a powerful player in supply chain strategy
	Huang and Iravani (2005)	Production policy under selective-information sharing.
	Stojanova et al (2013)	Mass customization of finished product.
Distributor	Ng (2012)	Information, quality, non-retrievable investments, goals, joint working and knowledge value.
	Chinomona and Pretorius (2011)	Trust, relationship commitment, relationship satisfaction and channel cooperation
	Djafar et al (2013)	Power of distribution channel.
Buyer	Cox (2001, 2007)	Power structure in procurement and supply management.
	Auka et al (2013)	Dimension of service quality involve tangibility, reliability, responsiveness, assurance and empathy.
	Soliman (2011)	Structural relationship on customers, customer knowledge management, and marketing performance.

Moreover, improving the productivity in a business process can be achieved with the appropriate relationship between manufacturer and other entities such as suppliers, distributors and buyers (Parvatiyar and Sheth, 2002). Thus, it is expected there are the sharing of information between entities through a system. It means manufacturer and other entities conduct joint forecasting and jointly decides on time and size of the delivery (Mukhtar and Shaharoun, 2002). On the other hand, few enterprises do not require yet arranging in order to collaborate relationship between manufacturer and other entities. The company tends to pick up the production based on orders because there is no information sharing (Huang and Iravani, 2005). According to Mleczko (2011), most of this type considers high of variant product. In addition, some manufacturer produces the customize product to the customer (Stojanova et al, 2013).

Supply chain strategy face problems more complex when product delivered using long distribution channel. To design the optimum distribution strategy, the firm required to consider transportation issue involving cost, variability and transportation service provider (Djafar et al, 2013). Power collaboration with the distributor to be crucial part should be considered. To keep the service quality to the customer, the relationship model can be made in the form of agreement that is approved by the firm and distributor (Kim and Mahoney, 2006). In addition, violation of the agreement in the contract gets the punishment because it damages the relationship to win the market. Moreover, Ng (2012) noted that the developing sustainable relationship with distributor enable mutual benefits and improve competitiveness in the industry.

The activity of business process is determined by the buyer requirement because manufacturers produce a number of products from information of the buyer and the demand based on production capacity (Duffy and Fearne, 2004). It means the buyer gives pressure in the place on a business. In addition, according to Cox (2001), reason of the buyer has the power to switches for another product is simple. Therefore, there is a small number of buyers influence the sensitivity of buyer price. Moreover, there are many dimensions that affected the power of the buyer. Auka et al (2013) studied in retail banking in Kenya. The results indicate that several the dimensions of service quality to the customer have a positive and significant influence on customer loyalty.

Halal Foods

Halal is derived from the Arabic language which means authorized, legal, permitted and allowed to any object or activity that is used or implemented in the religion of Islam. This term is most often used to indicate the food and drinks that are allowed to be consumed by Islam based on the kind of food and how to obtain it. Therefore, Islamic laws prohibit the consumption of alcohol, pork, blood, dead meat, and meat which has not been slaughtered according to Islamic rulings (Zulfakar et al, 2011). These laws are binding and must be observed at all times. Especially for foods, it is the most strictly regulated of all products in Islam. In addition, Zulfakar et al (2014) noted that many of the foods prohibited by religions on a temporary or permanent basis are of animal origin.

Nowadays, to identify the critical Halal foods, the industries is pushed to control their products with certified Halal products through HACCP (Hazard Analysis Critical Control Points) in order to ideally yields guaranteed and trustworthy halal credence quality of foods. Moreover, this method is a worldwide recognized and applied quality assurance system within companies situated at different levels of the agro-food chain (Tieman et al, 2012).

Halal foods represented a chain that mutually collaborate among supply chain actors and applied the same principles as conventional supply chain with special exception on the type of products that are been handled. Ab Talib et al (2015) revealed supply chain Halal food involves the process of planning, implementing and controlling the efficient flow and storage of Halal certified product from source to the demand point. It can be also referred to the process of managing the procurement, movement, storage and handling food products through the organization and the supply chain in compliance with the general principles of Sharia law.

Conceptual Framework of Supply Chain Halal Foods

This research developed the conceptual framework in managing Halal foods through power collaboration in between Supply Chain Actors. It is expected to give implications for any aspects such as industry, policy maker and scholar's knowledge in order to explore the concept supply chain Halal foods. Figure 1 shows the conceptual framework of supply chain Halal foods which it breakdown from SCOR dimension into power collaboration in Halal food processing.

SCOR Dimension	Power Collaboration	Halal Foods Processing
Source	Power of supplier	*Supplier* : - Breeding - Livestock Farming - Slaughter Process
Make	Power of manufacturer	*Manufacture* : - Meat Processing - Packaging - Labeling
Deliver	Power of distributor	*Distributor* : - Retailing and outlet - Transportation - Storage
Return	Power of buyer	*Buyer* : - Safety - Haelth - Quality assurance

Fig 1. Conceptual framework of supply chain Halal foods through SCOR model and power collaboration

The conceptual framework above focuses on the business process in of Halal foods which were then incorporated into the stages of process modeling using the SCOR Model. Although foods processing have similar the core business, they differed in operational strategy in production systems. Therefore, strategy of particular operations within the business process depended on type of collaborations in a supply chain (Miguel and Brito, 2011). Barber (2011) and Kähkönen (2014) revealed that there was some power position of collaborations in the strategy of the supply chain that affected the relationship between supplier, manufacturer, distributor and buyer. These relationships were constructed as power to emphasize certain supply chain actors. Thus, each actor can cooperate to optimize the supply chain network in order to reduce the costs of supply chain in the system (Mizgier et al, 2010).

Moreover, this conceptual framework found that power collaboration within supply chain actors in Halal Food is necessary to be considered in order to develop effective collaborations with the partnerships. Therefore, the actors must identify their own power position in the collaboration to provide the best service of Halal foods to the customer in run the business process. Noémi (2012) revealed in his study that the operation of a supply chain strategy cannot be described without investigating its collaborations.

Conclusions

This paper has explored in previous studies performed on the basis of the paper on Halal foods, supply chain strategy and power collaboration. As the result, this study has shown the development of a conceptual framework of supply chain Halal foods from a literature review to a conceptual framework. Therefore, the case study in Halal foods represented the supply chain of business processes that cooperate with other supply chain actors such as suppliers, manufacturers, distributors and buyers. To support this study, further research is suggested to consider other factors that can affect the supply chain Halal foods involving regulations for each region that implement the policy of Halal foods in greater detail. Moreover, the finding of this study should compare with the research

that success to adopt supply chain Halal foods in Islamic countries in order to validate this conceptual framework.

Abstract

Human activity recognition (HAR) is a very hot research topic in computer vision nowadays. Recently, numerous application (HAR) systems and approaches have been proposed. The prediction in human mobility using big data however still remains a challenge to the classification problem. This is mainly due to the huge variations, such as growing information amount and high dimensionality of data, the difficulty in modeling the precise relationship between the large number of feature variables, and the class variable. In such cases, it is highly desirable to reduce the information to a small number of dimensions in order to improve the accuracy and effectiveness of the classification process. Nevertheless, the performance of (HAR) is not high enough yet. This paper aims at improving the performance of human mobility modeling and mining by employing dimension reduction based on statistical techniques. The developed method has been applied on a new and publicly available human activities dataset. The obtained results are effectively interpreted, and the efficacy of the suggested method over the well-known methods is discussed.

Keywords: Dimension Reduction, Classification, Human Activity Recognition.

1. Introduction

With the rapid aging of the population, a reflection emerged around the technology providing practical solutions to the needs of the elderly, for home care, with enhanced safety and improved quality of life. Shares of recognition-based technologies arouse more interest because of their effectiveness. The tracking behavior and, specifically, the person's ability to perform everyday activities are important to detect the entry into dependence of the person and detect risky situations.

Human activity recognition generally comprises a step of extracting primitives and a classification step. The extraction of primitives is to identify distinctive characteristics while being robust to noise. In the classification stage, we are interested in the possibility of identifying the actions using machine learning methods, taking into account the variability that a class action may be exposed, especially if performed by different subjects and different kind of size and speed and different way.

Classification, one of the popular human activity recognition, has been applied in many areas of human decision-making. A number of methods and algorithms have been developed for human activity recognition problems, including statistical models, decision and regression trees, rules, connectionist networks, probabilistic networks. Supervised classification forms the core of what has been recently called the data mining. The methods originated in statistics in the early nineteenth century, under the Moniker discriminant analysis. The applications of supervised classification in real life are very vast, like human activity recognition, automatic speech recognition, face detection, signature recognition, customer discovery, spam detection, systems biology etc.

Nevertheless, in the last decades, the interest in the dimensionality of many classification problems has increased. Much of human activity recognition problems have provided results of high dimensionality, along with a substantially growing trend. One of the major current challenges concerning many classical classification algorithms is, dealing with large high dimensional data. At this stage, some of the increase in dimensionality, where the number of variables or features (p) and the number of samples (n) are greater, can affect the performance of classification algorithms. Examples of datasets

include text data, speech data and digital images often have thousands of features and hundreds of thousands or millions of objects. This makes it difficult or even impossible to apply supervised classification methods (e.g., logistic regression, discriminant analysis).

A general framework is therefore suggested for the structural (HAR) problem that can be formulated for dimension reduction and class prediction. This framework will be applied on a new and publicly available human activities dataset, and the obtained results will be interpreted and discussed.

2. Background

Among the branches of computer sciences, human activity recognition, artificial intelligence, and data mining are the branches which are related to each other and to statistics and mathematics. Their goal is to allow computers to perform tasks involving learning or reacting to data.

2.1. Human activity recognition

Computer vision is an exciting topic of research to develop the computer systems analysis and interpretation the visual capabilities of a scene close contents to those of human vision. One of the major objectives in computer vision is to recognize and understand human mobility, in order particularly to define the classification of human activities.

2.2. Dimension Reduction

The problem of dimensionality reduction can be defined by assuming that we have dataset represented in a $n \times p$ matrix 'y' consisting of n datavectors $y_{i_{(i \in \{1,2,\dots,n\})}}$ with dimensionality 'p'. Assume further that this dataset has intrinsic dimensionality 'k' (where$k < p$, and often $k \ll p$). Here, in mathematical terms, intrinsic dimensionality means that the points in dataset 'y' are lying on or near a manifold with dimensionality 'k' that is embedded in the p-dimensional space. Dimensionality reduction techniques transform dataset 'y' with dimensionality 'p' into a new dataset 'x' with dimensionality 'k', while retaining the geometry of the data as much as possible. In general, neither the geometry of the data manifold, nor the intrinsic dimensionality 'k' of the dataset 'y' are known. Therefore, dimensionality reduction is an attention-demanding problem that can only be solved by assuming certain properties of the data (such as its intrinsic dimensionality).

2.2.1. Dimension Reduction based Sliced Inverse Regression (SIR)

A parametric regression model describes the relationship between a dependent variable $y \in \mathbb{R}$ and a predictor $x \in \mathbb{R}^p (p \gg 1)$ with $\mathbb{E}(x) = \mu$ and $\mathbb{V}(x) = \Sigma$ of the form:

$$y = f_\theta(x) + \varepsilon,$$

Where 'f_θ' belongs to a family of functions parameterized by 'θ' (vector parameters real) and 'ε' is a random error term. In this type of model, the ultimate goal is to estimate the parameter 'θ'.

The parametric estimation techniques (methods of maximum likelihood and least squares for example) are efficacies when the family 'f_θ' is correctly specified. However, in many applications, highlighting a suitable parametric model is not simple. Also, when a parametric model is not available, the nonparametric regression techniques appear as an alternative, providing the desired flexibility in modeling. In that case, the above mentioned relation is transformed into:

$$y = f(x) + \varepsilon \ ,$$

Functional regression is based on a local smoothing that utilizes the properties of continuity and differentiability of the regression function 'f'. The quality of the local smoothing at a point, therefore, depends on the presence of sufficient data in the vicinity of this point. When the variable is univariate ($p = 1$), we can mention among others the method cores or smooth splines. However, when the dimension of 'x' becomes large, the number of observations required for the local smoothing grows exponentially with dimension. So unless you have a huge sample size, these nonparametric methods are no longer appropriate due to the low number of points in the region of interest.

To overcome this problem known as the "curse of dimensionality" some methods for dimension reduction suppose that 'x' can be replaced by a vector of dimension 'k', strictly less than 'p', without losing information on the conditional distribution of 'y' at given 'x'. The corresponding model assumes dependency between the predictors, and the response variable is described by linear combinations of predictors.

2.3. Linear Discriminant Analysis (LDA)

Linear Discriminant Analysis or (LDA) method is a statistical discriminative way. Let the probability that an element with measurement vector 'y' belongs to group 'g' is $P(g_i|y)$.

We consider the set of distributions $\{P(g_1|y), P(g_2|y), \ldots, P(g_N|y)\}$ which are multivariate normal distributions $N(\mu_i, \Sigma_i)$ with the common variance:

$$\Sigma_1 = \Sigma_2 = \ldots = \Sigma_N = \Sigma \ ,$$

Each element is classified into the group 'g_i' where the posterior probability $P(g_i|y)$ that it is a member of that group, given its value of y, is the largest. (LDA) applies Bayes formula to evaluate $P(g_i|y)$ using $P(y|g_i)$ and the prior probability $P(g_i)$. This posterior probability is calculated using Baye's rule as: $\mathrm{p}(g_i|\mathrm{y}) = \frac{\mathrm{p}(y|ig_i)\mathrm{p}_i}{\Sigma_{k=0}^{N}\mathrm{p}(y|g_j)\mathrm{p}_k}$, Where '$p_k$' is the prior probability that a case is a member of group 'k'.

3. Methods

A general framework is suggested for the structural (HAR) problem that can be formulated for dimension reduction and class prediction. Under this framework, our procedure consists of two basic steps (Fig 1): the first step is dimension reduction, in which data are reduced from higher p-dimensional vectors space to a lower k -dimensional factor space. The second step is the construction of learned model for human activity prediction, in which response classes are predicted using a class prediction method on the extracted factors.

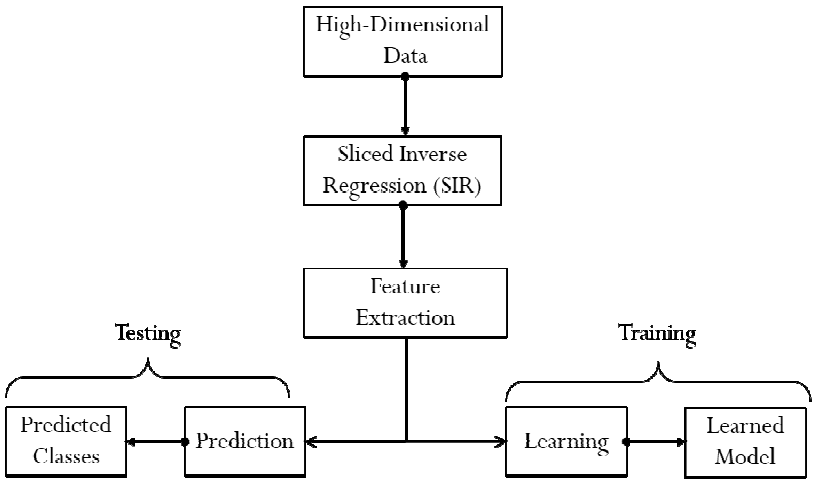

Fig 1: A dimensionality reduction framework (HAR)

3.1. Dataset and Preprocessing

The established algorithms are applied to a publicly available dataset 'Human Activity Recognition Using Smartphones Data Set'. HAR-database built from the recordings of 30 subjects performing activities of daily living (ADL) while carrying a waist-mounted smartphone with embedded inertial sensors. The dataset contains 561 attributes with 10299 instances. The experiments have been carried out with a group of 30 volunteers within an age bracket of 19-48 years. Each person performed six different activities (walking, walking upstairs, walking downstairs, sitting, standing, laying) wearing a smartphone (Samsung Galaxy S II) on the waist.

3.2. Feature Extraction

Although the procedure described here can handle a large number of attributes, it may still be too large for practical use. While, the model assessment procedure requires fitting the data many times, it is very time-consuming process due to cross-validation and re-randomization. In addition, a considerable percentage of attributes do not show differential expression between the groups and only a subset of attributes is worthy of interest. A dimension reduction is performed in this study, for function extraction by sliced inverse regression (SIR).

3.3. Class Prediction

The high dimension of 'p' is then reduced to a lower dimension 'k' after dimension reduction. The original data matrix is constructed by a matrix of factors ($n \times k$, where $k < n$), constructed by (SIR), as described in the previous section. Once the k-factors are composed, prediction of the response classes using linear discriminate analysis is taken into consideration.

4. Results and Discussion

The interest of dimension reduction by considering applications for the class prediction of HAR-data has been illustrated. We compare the results produced by our procedure with the performance of the direct classification approach.

4.1. Application to HAR-Dataset

After data preprocessing, the proposed performance evaluation procedure on the HAR-dataset is applied. We choose 8000 instances randomly to train model and the 2299 remainder instances are used to test the model. Table 1 gives the estimates of common factors 'k' after the dimensionality reduction and the classification accuracy performances.

Table 1- p: number of selected variables; k: estimated number of factors.

Dataset	p	Reduction model	k	Classification model	Classification accuracy %
HAR	561	SIR	**61**	SIR-LDA	98,49
			26		93.46
			15		92.35
	561	PCA	**61**	PCA-LDA	98,04
			26		92.89
			15		92.22
	561	Pristine	**561**	LDA	98.31

4.2. Discussion

In this paper, the possibility of dimensionality reduction by employing dimension reduction based on sliced Inverse regression (SIR) to solve the course of dimensionality problem arising in the context of big data is explored, and its performance in class prediction framework for human activity recognition using LDA is evaluated. A priori, LDA can handle a large number of variables. However, as many other multivariate methods it is challenging due to large computational time and risk of over-fitting. Therefore, dimensionality reduction for many variables so as to reduce the large computational time has been used.

Table 1 represents the results obtained by applying the three models; SIR-LDA, PCA-LDA and LDA on the experimental dataset. Concerning dimensionality reduction task, three different criteria to estimate the number of common factor have been defined. The first criterion is the higher eigenvalue to one which provides us 61 common factor, the cumulative variance equal to 80% as the second criterion, which produces 26 common factor. After dimensionality reduction the results of class prediction show that, for $k = 61$ the best accuracy is obtained by SIR-LDA model 98.49 %, which is followed by PCA-LDA model 98.04 %. For $k = 26$ the highest accuracy is obtained from SIR-LDA model, and then PCA-LDA model with values 93.46 %, 92.89 % respectively.

In the case of third criterion, the number of common factors from the best classification accuracy is evaluated which provides a near classification accuracy of second criterion (93.46%) and the respective 'k' is lower than 26. The results demonstrate that the achieved accuracy is comparable with the other two criteria, furnishing k=15. For the excellent classification accuracy, SIR-LDA model 92.35% is obtained, which is pursued by PCA-LDA model with 92.22% accuracy. It is evident that the number of common factors are equal to quarter of the first criterion, and about half of reduction has been accomplished in comparison with the second criterion, inferring the efficacy of the proposed framework. The descending order of the number of common factors can be described as following:

$$\boldsymbol{k_{SIR-LDA} < k_{PCA-LDA} \ll P_{LDA}}$$

5. Conclusion

This paper reports an efficient dimension reduction approach for the class prediction related to the human activity recognition. The proposed algorithm performs dimensionality reduction with two processes, i.e. the SIR-based dimensionality reduction and the PCA-based dimensionality, and the obtained results are compared, interpreted, and discussed. The principle advantage of this approach is that the number of features can be remarkably reduced from p=561 to k=15 for HAR-dataset, with a fine classification accuracy (92.35%). In addition, the suggested method is capable of addressing some crucial dimensionality reduction issues as well. The application of the proposed method on the experimental dataset results in the achievement of the best performance for dimensionality reduction (in terms of least time consumption and CPU-expenditure). It is also emphasized that the suggested method appears to be more effective than the well-known methods of its kind, and it may possibly be generalized on different types of machine learning with the reduced data.

The Impacts of IT Capabilities on Teaching and Learning Mathematics: A Conceptual Framework for Malaysia

Lew Sook Ling, Multimedia University, Jalan Ayer Keroh Lama, 75450 Melaka, Malaysia, sllew@mmu.edu.my

Yuen Yee Yen, Multimedia University, Jalan Ayer Keroh Lama, 75450 Melaka, Malaysia, yyyuen@mmu.edu.my

Abstract

The steep fall of mathematics performance of Malaysian students in International Mathematics & Science Study (TIMSS) 2011 signaling urgent needs to ensure effective teaching and learning in mathematics. The insufficiency of Information Technology Capabilities (ITCs) is a major challenge for teaching and learning mathematics in Malaysia. The key objective of this research is to propose a comprehensive framework, which incorporates crucial ITCs such as collaborating, data management, dynamic and integrating capabilities for Malaysian schools to improve mathematics performance. A systematic literature review (SLR) was carried out to design the appropriate ITC framework for teaching and learning mathematics. Based on the findings, an applicable model for representing and reasoning about ITC in improving mathematics performance will be designed. This study is particularly important to assist Malaysian government to achieve one of the key aims of Education Malaysia Education Blueprint 2013-2015 and National Key Results Areas (NKRA), which is to provide quality Mathematics education to all Malaysian students. Since currently there is a lack of established framework and IT application in Mathematics education, the outputs of this study will be served as the preliminary confirmation of integration of ITC to mathematics education.

Keywords: Information technology capability, IT, Performance of mathematics, Technology integration in teaching and learning, Malaysia.

1. Research Background

The results of Malaysian students have declined severely in International Mathematics & Science Study (TIMSS) among all tested countries; remarkably in Mathematics subject. The ranking of Malaysia was dropped from 20th in 2007 to 26th in 2011.

The average mathematics score was “above average (474)” in 2007 and “below average (440)” (TIMSS 2013). Meanwhile, the gap between Malaysian students’ outcomes of high performing schools and low performing school is also widening and worrying.

Although the integration of information technology (IT) in mathematics education has widely accepted and supported by researchers, practitioners (Drijvers, et al, 2014; Sam, et al, 2009; Wen & Yu, 2012) and Malaysian government (Ministry of Education (MOE), Malaysia, 2012); the ways of integration of proper ITCs in mathematics in Malaysia is still at the infancy stage (Sam, et al, 2009). One of the difficulties of integration is the lacking of IT resources and IT capabilities (ITCs) in mathematics (Chong, et al, 2005; Drijvers, et al, 2014). Hence, the findings of this study could address the appropriateness of using ITs (when teaching and learning mathematics) by identifying the ways of integration in the school system (Chong, et al, 2005). Furthermore, very few works on the application of causal knowledge-driven approach in student performance analysis; in particular, learning causal models from survey data. In this study, the author introduces learning Bayesian networks from survey data as an applicable model for representing and reasoning about ITC in improving mathematics performance. These steep fall results depict a comprehensive framework using ITCs to improve performance of Malaysian students in mathematics is crucial. A special ITC framework for high school is fortunate to develop to address this pressing issue.

Therefore, this study is conducted to address the appropriateness of using IT when teaching and learning mathematics and integrate IT capability (ITC) in the mathematics education of current high school system.

Objectives of Research

The overall goal of this study is to determine the impact of information technology capabilities (ITCs) on teaching and learning mathematics. Specifically, this study is to answer the following research questions:
1. What are the appropriate information technology capabilities (ITCs) to improve performance of teaching and learning mathematics?
2. How do ITCs affect performance of teaching and learning mathematics?
3. How to integrate ITCs in the mathematics education of current high school system?

Significance of Research

The developed framework is aimed to improve the mathematics performance. This aim is in line with the aspiration of Malaysia Education Blueprint 2013-2015, particularly in the area of Education National Key Results Areas (NKRA), in which providing quality education to all Malaysian students and enhancing school system and results.

The teaching and learning difficult mathematics lessons can be conducted effectively with the developed IT application that incorporated all the IT capabilities from the developed framework. While mathematics being a fundamental knowledge for all disciplines, improving student outcomes in mathematics could develop further viable and sustainable workforce while transforming Malaysia to a developed nation by 2020.

Furthermore, using the developed IT application particularly in low performing schools can improve the mathematics performance in overall. This expected outcome is tied in closely with NKRA's aim which to "reduce the number of Band 6 and 7 schools by 20% and increase the number of Band 1 and 2 schools by 8% in the course of the GTP" (Ministry of Education (MOE), Malaysia, 2014).

2. Literature Review

Mathematics Education with Information Technology (IT)

In recent years, researchers and practitioners (Drijvers, et al, 2014; Sam, et al, 2009; Wen & Yu, 2012) have paid attention to the positive impacts of teaching and learning mathematics using information technology (IT). The Ministry of Education (MOE) believes that the integration of information and communication technology (ICT) is an essential component for providing quality education to all Malaysian students and enhancing school system and results (Ministry of Education (MOE), Malaysia, 2012).

However, the ways of integration of proper ITCs in mathematics in Malaysia is still at the infancy stage (Sam, et al, 2009). Hence, when teaching and learning mathematics, the appropriateness of using ITs in the school system nurtures the latest issues among researchers and practitioners.

With special consideration to Malaysian high school context, this study tries to answer these questions generally based on the three most useful ITCs in mathematics educational perspectives. The three most useful ITCs described IT as: "(1) tools that help students accomplish more, (2) can be used for interesting simulations students can learn about through exploration and interaction and (3) offers new ways of structuring the curriculum to both support student inquiry and cover more content" (Ferbar & Trkman, 2003).

Information Technology Capability (ITC)

Knowledge acts as a foundation for knowledge management (KM), KM activities and information technology capability (ITC). Sequentially, both ITC and KM activities are reinforced by IT resources (Tanriverdi, 2005). Sher and Lee (2004) demonstrated that IT resources lead to larger ITC frequently. Performance resulting from the development and utilisation of IT resources was investigated (Chang & Chuang, 2011; Jee-Hae, et al, 2012) and the primary finding showed that organisations that possessed ITC often enjoyed better performance.

Adopted from Lew and Yuen (2014), ITC is opeationalised as a group of capabilities; detailed as:
1. Collaborating capability,
2. Data management capability,
3. Dynamic capability and
4. Integrating capability.

Many ITCs cannot be replicated in other ways such as "the capability of visual and digital media which are displayed through animation, audio/ visual, simulation, or interactivity especially those media involving the students to participate" (Pope, 2013). Therefore, this research aimed to connect the teaching and learning mathematics in classrooms with the media-rich world to improve mathematics performance.

Adopted from Pope (2013) who describes ITC as "the capability of visual and digital media which are displayed through animation, audio/ visual, simulation, or interactivity especially those media involving the students to participate"; there is a significant relationship between IT resources (visual and digital media) and IT capabilities (Collaborating capability, Data management capability, Dynamic capability, Integrating capability). Hence, the following hypothesis is outlined:

H1: There is a significant relationship between information technology resources and information technology capabilities (ITCs).

Independent Variable (IV) 1: Collaborating Capability

A German automotive supply chains would be benefited from collaboration capability in organisational operation (Wiengarten, et al, 2010). Timeliness, accuracy, relevance and value added on information-distribution and collaborative accomplishment were among the enhanced information. Common collaborating tools consist of blogs, bulletin boards, calendars, corporate portals, discussion groups, document sharing, email, instant messaging, project workspaces, SMS, task lists, wikis (Christopher, 2006; Tinker, et, al, 2007). As an example, a sharing platform such as corporate portals can give organisational members a common place for collaborative works (Benbya, et al, 2004). With collaborating capability, collaborators perform better for a sharing and common work (Minkyun, 2010) as well as mathematics education (Tinker, et al, 2007). In this study, "collaborating capability refers to the ability of linking students so that they can learn together and the teachers can share their teaching materials or methods together".
The following hypothesis is formulated:

H2a: Collaborating Capability affects performance of mathematics.

IV 2: Data Management Capability

Data is initially meaningless. Changing a meaningless data to meaningful data, a series of processes such as "stored, grouped, analysed, processed and summarised" is needed. According to Zack (1999), "knowledge consists of data and information that has been processed to produce understanding, experience and expertise in a particular circumstance". In view of the fact that knowledge is sourced from data and information (Ngai & Chan, 2005), organising and processing knowledge are essentially the activities of knowledge management (KM). For this reason, "data management is operationalised as the capability to manage any data that related to learning and teaching mathematics" (Tinker, et al, 2007).

This data management capability comprises the capability of managing database management systems and storing data (Kim, 2001), transacting data, tracking data, analysing data and translating data (Zack, 1999). Hence the following hypothesis:

H2b: Data Management Capability affects performance of mathematics.

IV 3: Dynamic Capability

Dynamic capability is defined as "the capability to confront external challenges through organisational flexibility and the ability to integrate, build and reconfigure internal and external competencies" (Alavi & Leidner, 2001). Organisations and individuals must be greatly adaptable and innovative for the period of speedy technological revolution. In international marketplaces, this capability of quick to response is very much required to challenge unpredictable environmental changes (Evers, 2011). Hence, dynamic capability is needed to enable rapid adaptation in any unpredictable changes for students and teachers in their learning and teaching. Hence, the following hypothesis is outlined:

H2c: Dynamic Capability affects performance of mathematics.

IV 4: Integrating Capability

Diverse data and resources are available across organisations; particularly knowledge and technology intensive organisations. These diverse data and resources provide assorted and distributed organisational knowledge and information which required to be united in its place (Benbya, et al, 2004). With the wide variety of references such as text books, notes and audio visual materials, the integrating capability enables teachers and students access and utilise mathematics knowledge effectively throughout the schools (Alavi & Leidner, 2001; Tinker, et al, 2007). In brief, "integrating capability refers to the ability of linking individual components and services for the purpose of sharing knowledge, communication and data resources" (Kim, 2001). Hence the following hypothesis:

H2d: Integrating Capability affects performance of mathematics.

As described in above paragraphs, although every IIC is distinctive but greatly interconnected. The IICs facilitate and reinforce each other (Lew, et al, 2015). Therefore, in this study, ITCs are considered as the foundation for teachers and students in teaching and learning of mathematics.

3. Methodology

This study used systematic literature review (SLR) to collect the secondary data. As for primary data that is customised for Malaysia, pilot survey will be carried out and followed by actual survey.

Pilot Survey

Based on the review of literatures, a research questionnaire will be developed as instrument to answer the research questions. A pilot survey of 5 teachers and 20 students will be conducted to measure face validity and reliability of the developed questionnaire. 5 mathematics teachers. The suggestions and comments from the pilot study will be evaluated and incorporated into the survey prior to the actual study. The revised questionnaire will then be sent to 5 information system experts for further reviews. These experts will be senior lecturers in academic institutions.

Actual Survey

Focus group study will be conducted to identify key information technology capabilities (ITCs) that influence mathematics performances of high school students, followed by a questionnaire survey of 250 teachers and 250 students to determine the relationship between ITCs (cause) and mathematics results (effect).

Based on this actual survey results, mathematics lessons will be delivered to 2 different groups of students “with” and “without” the IT application. Mathematics performances of both groups of students will be compared to verify the effectiveness of the proposed ITC model and IT application in improving students’ mathematics performances in high schools.

Data Analysis Techniques

The application of causal knowledge-driven approach in student performance analysis; in particular, learning causal models from survey data will be used in this study. An applicable model for representing and reasoning about information technology capability (ITC) in improving mathematics performance will be designed from learning Bayesian networks from survey data. Bayesian Network is a network representation or graphical representation that represents conditions that affects decisions by assisting to solve problems in the domain. Bayesian networks offer good analysis for model-based domain descriptions and represents knowledge in situations involving updating a belief. Bayesian networks are essential in various fields for decision support and are capable to provide causal knowledge based on data domain, experts’ knowledge domain or Bayesian classification.

Bayesian networks are directed cyclic graphs with nodes as random variables and arcs that indicate causal interpretation. Bayesian causal maps were described to represent and analyse domain knowledge of experts (Nadkarni & Shenoy, 2001). Bayesian causal maps are Bayesian Networks that graphically represents expert’s knowledge for probabilistic causal reasoning (Verma & Pearl, 2013). It states that Bayesian Networks are the design of a joint probability distribution of several variables in terms of conditional distributions for each variable. Bayesian Networks enable the use of causal maps to make inferences to facilitate decision-making under uncertainty, ambiguity and incompleteness. The evidence of Bayesian networks rely on the observation of specific state. A situational example of a Bayesian Network implies A -> B -> C whereby A directly causes B and B directly causes C.

4. Proposed Framework

The proposed framework is presented in Figure 1.

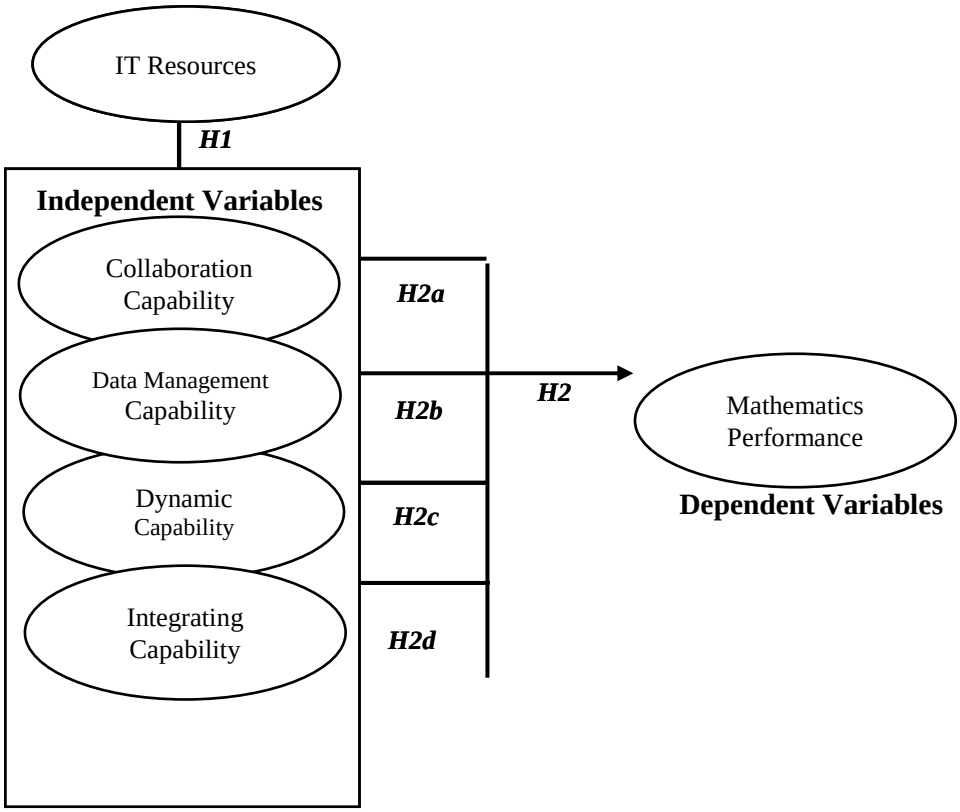

Fig 1. Proposed Research Framework

Notes:

H1: There is a significant relationship between information technology resources and information technology capabilities (ITCs).

H2 is a set of collective hypotheses of all the 4 information technology capabilities (ITCs) as follows:

H2a: Collaboration Capability affects performance of mathematics.

H2b: Data Management Capability affects performance of mathematics.

H2c: Dynamic Capability affects performance of mathematics.

H2d: Integrating Capability affects performance of mathematics.

Summary of Variables

The information technology capability (ITC) is the independent variable. Mathematics performance is the dependent variable. ITCs are conceived as "cause", which influence mathematics performance as "effect". Consequently, students that have high can learn mathematics effectively to achieve higher mathematics performance which will be reflected in better academic results.

Table 1 summarises the variables and sources.

Table 1: Summary of Variables

Item	Variables	Sources
Independent		
IV	Information Technology Capabilities (ITCs)	
	IV1: Collaboration Capability	(Benbya, et al, 2004; Christoph 2006; Minkyun, 2010; Tinker, et 2007; Wiengarten, et al, 2010)
	IV2: Data Management Capability	(Lew & Yuen, 2014; Ngai & Cha 2005; Tinker, et al, 2007; Zack, 1999
	IV3: Dynamic Capability	(Alavi & Leidner, 2001; Evers, 2011)
	IV4: Integrating Capability	(Alavi & Leidner, 2001; Benbya, et 2004; Tinker, et al, 2007)
Dependent		
DV	DV1: Mathematics Performance	(Drijvers, et al, 2014; Sam, et al, 200 Tan, et al, 2015; Wen & Yu, 2012)

5. Conclusion

In this study, the author has reviewed previous studies of integration of information technology capability (ITC) in mathematics education. Lacking of IT resources and ITCs in mathematics are among the core constraints of integration IT in mathematics education. Therefore, based on the results of survey and Bayesian network analysis, an IT application will then be developed. It is hoped that by knowing and integrating the appropriate ITCs in mathematics education, the mathematics performances can be improved.

Abstract

For several years social media is becoming more and more popular and famous in the 21st century. Especially so-called social media networks are having huge relevance in daily (online) business. But nowadays many small and medium-sized enterprises (SME) are facing the missing practical and feasible solutions how to integrate and implement social media activities in their current structures. This is based on the fact that many German medium-sized companies are facing difficulties with social media business. On the one hand this is based on the fact that there is no know-how about the possibilities of social media activities. On the other hand this is based on the fact that there are no resources and the big fear of wrong investments into tools concerning Web 2.0. Social Media is a very complex topic. With regards to the changing environments and fast moving online Web 2.0 conditions, companies need to face social media activities increasingly. Within the given research paper - which carries exclusively the secondary data approach - only some of the basic tools were introduced. It needs to be taken into account that there a much more tools. It is highly recommended to face all corresponding influence factors in order to avoid a poor performance and implementation.
Keywords: Social Media, Networking, Blogging, SME

1 Introduction

For many years, classical marketing tools are used over generations to support many companies and brands to build brand awareness and to strengthen sales activities. Known worldwide, the so called Porter's 4 P's set the foundation for many marketing activities and strategies. But in the last years a new digital "communication tool" occurred and gained big power/ relevance: Social media. Social media usually refers to the term Web 2.0 and is used throughout daily business worldwide.

In general, social media connects brands, organizations, customers and potential partners effectively. And there is one bigger advantage: Social media mainly targets other customers through the shift from pontification to a two-way communication, rather than classical marketing. This means that consumers do not only trust in classical marketing or in classical messages and no longer believe in corporate messages. Rather, customers want their information from people / groups they know, they believe and trust in. These social media aspects count on the fact of building relationships which are more lasting and will result in higher sales, less returns and greater word-of-mouth impact. But this competitive advantage needs to be prepared and implemented in order to have this advantage.

Therefore, the given research paper provides a brief introduction of the basic social media tools which small and medium sized enterprises might have to take into account. Due to the fact that social media cannot stand alone but needs to be considered within an integrated marketing strategy, the paper

can be seen as a first guidance for companies and their marketing managers who are considering social media in the near future.

Since this research paper is in progress, it needs to be taken into account that there are more social media tools than mentioned in the given paper as well as the fact that not all tools might fit a company´s marketing - and overall presence - strategy.

2 Social media

In order to understand the importance of social media, it is necessary to approach and define the basic knowledge of social media first in order to get an understanding of the topic. Therefore, a short insight into the main guidiance and keyfactors of social media will be outlined. These keywords briefly cover the features of social media and provide the basis to analyse the relevance of social media.

2.1 Approaching the topic – What is social media?

Following Safko (2012, p. 4), social media is defined as the media which is used to be social. This means that hundreds of technologies which are available for someone to connect with someone else are used. The terminology social media consits of two parts.

The first one, *social*, "refers to the instinctual needs we humans have to connect with other humans" (Safko 2012, p. 4). This behaviour goes back to the point when the species began. Human beings try to be in groups and around with other human beings of similar like-minded people. This is based on the fact that these people or groups are feeling the same and sharing their thoughts, ideas and experiences (Grabs and Bannour 2014, p. 25).

The second terminology, *media*, defines the connection of how human beings get connected. This connection can be any possible way to get connected, for instance by written words, audio, web, television, email etc.

Combining the two terminologies, Bernecker and Beilharz et al. (2012) define social media as the process of how all these technologies can effectively be used to reach out and connect with other humans. Safko (2012, p. 4) goes even one step further and states that human beings then create a relationship, build trust and eventually these relationships develop to the point that the people become customers and buy the offered product. In order to clearly define social media, Meyer (2012, p. 10) highlights that social media generally solves not the marketing woes of companies and create instantly wealth for all involved parties. It is fundamental to question whether a company wants to do marketing and how much it is willing to spend. Social media is not seen as the solution for companies facing difficulties with current marketing activities. Following Safko, "social media is only a new set of tools, new technology that allows us to more efficiently connect and build relationships with our customers and prospects." (Safko 2012, p. 5)

Before defining the different categories and tools of social media, it is indispensable to question why social media should be used. Ever since the human beings began to interact, they pontificated. Nowadays, social media is seen as a two-way communication. Safko (2012, p. 5) defines the change as a shift from pontification to a two-way communication. This means the consumers do not trust classical marketing, classical messages as well as the fact they no longer believe in corporate messages. The customer rather want their information from people / groups they know, they believe and trust in (Heymann-Reder 2011, p. 22). With this shift there is a new way to communicate by listening first, following and understanding the conversation and only speak at the end (Hettler 2010, p. 26).

Coming back to the introduction and definition part, social media is mainly used for marketing, sales, public relations, and communication tools to communicate with the customers. Furthermore, social media is defined as a set of highly effective tools for customer service, business-to-business (B2B), and internal communications (Safko 2012, p. 8). Kerpen defines social media as a must have in customer service since it is the perfect tool to stay connected with the customers after sale. On the other hand on

the B2B side, social media has to be an integral part of the company's strategy as the majority of customer benefit from it in the B2B and the B2C business as well - if only certain information would stay password-protected online. The last parties are the internal customers such as the employees. Social media is a perfect tool to communicate with the employees and get connected with them easily (Kerpen 2015, p. 14).

Figure 1 gives a brief overview of the corresponding social media tools which will be discussed in the following research paper more in detail (Rating and Reviews, Blogging, Social Networks and Media Sharing).

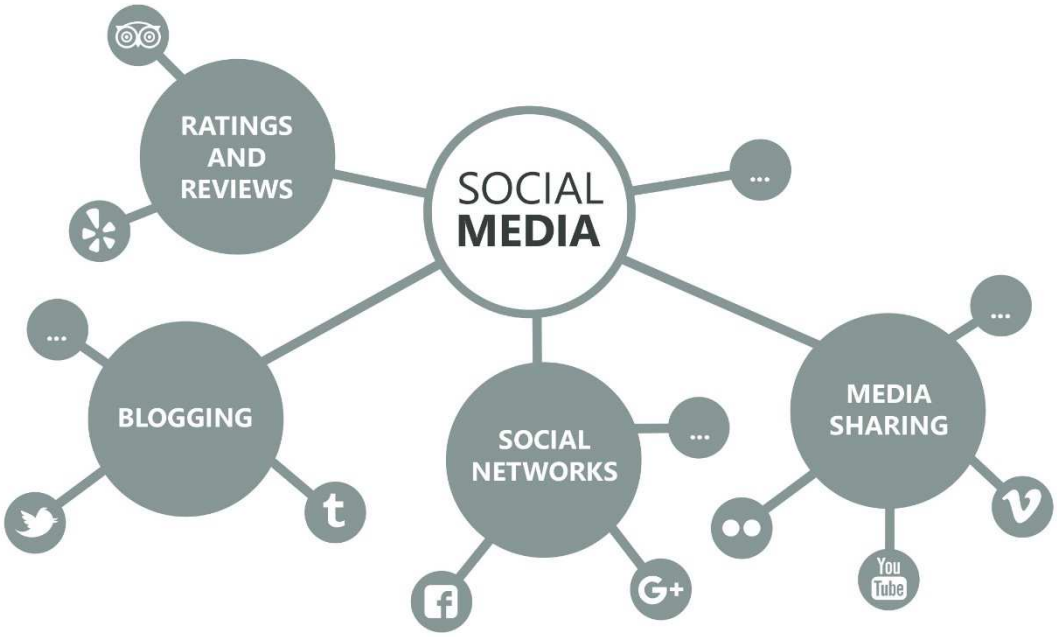

Figure 1: Overview of Social Media tools

2.1.1 Blogging

In order to understand micro blogging, the term blogging will be defined first. Blogging started in 1999 when the two companies called LiveJournal and Twitter were launched. Only nine years later, at the end of the year 2008, 346 million people were reading blogs, and 184 million started their own blog (Safko 2012, p. 11). Following Wolff, a blog is defined as a type of content management system (CMS) which allows anyone to publish short articles, so called posts. Posts can have any lengths between 100 words up to many pages but should always stick to one topic. Wolff emphasizes the language should be conversational in tone and not corporate-speak press (Wolff and Panter 2013, p. 38). The so called blogging platforms share common traits and features that make them blogs (Meyer 2012, p. 12).

There is certain blog software which provides a variety of social features (e.g. blogrolls, trackbacks) in order to make blogging perfect for marketing purposes. Besides, blogs can be integrated in nearly every other platform and tool and make it a big hub for other social media marketing efforts. For companies it can be seen as a perfect opportunity to blog on news affecting the industry and catch therewith customer's attention for free (Wolff and Panter 2013, p. 40).

Micro Blogging

Micro blogging is a form of blogging. The only difference is the limitation of the size of the post. For instance, Twitter (one of the famous micro blogs) updates are limited to 140 characters (Hilker 2010, p. 37). This spawned a set of features which are entirely unique to the medium and helped Twitter to become more mainstreamed than any other comparable social media tool (Zarella 2012, p. 31). Only a valid email address is required to set up an account which is necessary to log into the password required area (Barker et al. 2013, p. 210).

Safko (2012, p. 257) states there are many reasons for people to contribute to social and knowledge-sharing networks like blogs. Usually people get motivated to contribute once they experienced useful support or information and recognition. Some other contribute to share information and provide the community with valuable information (Grabs and Bannour 2014, p. 173). Anyone can microblog without limits and can read posts from other like-minded bloggers. Micro blogging includes the ability to send messages and / or audio, enables the users to even attach files and make friends, purchase products and services online, get directions and above all - there are no real limits for users. "Micro blogging is the epitome of social media two-way communication." (Safko 2012, p.258) Micro blogging began with the advent of blog. But over the time detailed long-spend conventional blogs turned into microblogging as it is much faster, easier and immediately accessible. (Barker et al. 2013, p.209).

Twitter was launched in March 2006 and was used right from the beginning for sending messages, from so called conferences-goers to find one another and to comment on panel sessions in real time (Grabs and Bannour 2014, p. 227). Everyone can set up an account on Twitter for free, either a personal or company account. The settings on Twitter allow each member to customizes their account (Barker et al. 2013, p. 216). One big advantage is the space for additional information and other social sites/links (Meyer 2012, p. 14).

2.1.3 Social Networking

Social network is defined as a website where people are connected with friends. Every social network has its own possibilities and challenges (Barker et al. 2013, p. 179). Users have different expectations of commercial behavior and require certain opportunities. Besides, these networking sites are hot topics for marketers since they present a number of opportunities for interacting with customers. Moreover, these sites include the possibility of plug-in applications, groups, and fan pages (Zarella 2012, p. 53). Safko (2012, p. 24) goes one step further and defines social network as a group of people who interact through several media (newsletters, comments, e-mail, telephone etc.). These groups use audio, photographs and videos for social, professional, and educational purposes to build trust in a given community. Their level of interaction and participation differs among the members.

The history and roots go back to the early 1980s where the first users could log in to systems to share software and data as well as sending messages and post on public boards. Due to slow connections and high costs of long distance calls, these networks were mainly local communities. With the growth of the World Wide Web, the social network became more popular and the first social networking pages were set up (Weinberg 2014, p. 199). Since 2009 the most popular and worldwide known one is the social network *Facebook.*

Facebook (www.facebook.com) started as an exclusive network for students of Harvard in 2003 and has become the most dominant social networking site in the last years. According to Wiese (2016) 28 million people are using Facebook in Germany whereof 21 million people use it every day. Out of the 28 million, 24 million people use Facebook on mobile devices. Compared to other social networks, Facebook has the most useful features for social media marketer.

Facebook is seen as a funny playground and an easily to navigate place to get reconnected with old friends (Weinberg 2014, p. 167). Besides, Facebook also offers privacy settings right after setting up the account. The user has the chance to divide his friends into lists, such as family, work, online buddies etc. and can control / specify therewith which features are seen by which groups (Palme 2012, p. 17).

With regards to companies, Facebook allows businesses to create public profiles known as *pages*. Some of the features are the same as the user profiles. The pages are for free and can have custom applications, photos, public messaging walls, and events (Calleen 2012, p. 58). Palme (2012, p. 84) emphasizes companies have to have a Facebook page if they are engaged in social media marketing since it can serve as a central place to integrate other marketing campaigns. When setting up a page for business, it has to have a few applications to make the page more interesting to visitors. This also increases the like hood for visitors to return again to the page. The best pages are set up by fans, not by companies (Zarella 2012, p. 67).

Once the user becomes a member of a social network, the lifecycle varies from user to user. The life cycle starts with initiating their life in a community as lurkers, visitors, or trolls. As soon as users become comfortable, they begin to participate in the community (Barker et al. 2013, p.184). Depending on the user and after a certain time of contribution, some members become regulars and some others break through to leaders. The time to become a so called “elder” depends on the culture of the site (Safko 2012, p. 25).

Depending on the feature sets and reasons to enter a social network, there are some common elements across most of the social networks (Hilker 2010, p. 31). All social networks are built up with user pages, known as *profiles*. Every user can decide on her / his own which information (name, education, relationship status, contact information etc.) in his profile is shared with the community (Zarella 2012, p. 57).

Against this background it is important to highlight, that social network profiles are for real people. Following Wolff and Panter (2013) a person should have a profile; a company’s logo should not have one as profiles contain personal information. Brands cannot have a favorite movie or hobbies. But brands can stick to a page or group for the company’s information (Barker et al. 2013, p. 197).

Coming back to basic idea of social networks, the most important action of social networks is the act of two people connecting. Following Zarella (2012) social networks are conceived to emphasize strong connections between people. People - the user should know in real life. Depending on the user, the user accepts friend requests from people the user know well, other user accepts friend requests from people they do not know well or they do not know at all. All social networks impose limits. There are restrictions on how many people you can connect in a given amount of time. This is based on the idea that these social networks are a building process (Zarella 2012, p. 59).

Since social networks are not recommended for brands but for persons, it is to be questioning how companies can generate profit from these huge social networks.

Many social networks contain the concept of a group. Following Zarella (2012, p. 63) a group is defined as a collection of people joined by some common interest. Within these groups the group members can share information and discussions, as well as sending (private) messages to each other. Starting and joining groups is simple and requires only little time and resources. The disadvantage, which has to be faced, is there are many people who belong to tons of pointless groups. The exception of network is Xing as this network displays the logo of the group on the user profile which is seen by all other users. This means that many users are becoming more selective with joining groups. Another important point for companies is the category photos. This feature allows the user to share and link pictures (Weinberg 2014, p. 306).

2.1.4 Media Sharing

Media sharing will be the penultimate tool which will be briefly introduced in the context of social media. So called user-generated content (UGC) allows users to create and upload multimedia contents on media-sharing sites. Nowadays this is a popular way to upload videos and pictures easily. Especially for marketers this idea is brilliant as they can create videos, upload these to certain websites and reach millions of users shortly (Barker et al. 2013, p. 143). Merz goes one step further and defines photo sharing as fun. A picture is worth a thousand words (Merz 2015, p. 34). The high-quality and low-cost

exposure is a perfect match to integrate photo-sharing in the business and marketing plan. Uploading is for free and once the pictures are online, the company participates in the web and reaches out to millions of people (Heymann-Reder 2011, p. 195). Another advantage is that all (product) pictures can be uploaded, and can therewith perfectly complement the assortment of a company's product range online. According to Safko, there is a differentiation between pictures and video recording and uploading. Video recording is called video or *vlog* as the word blog stands for "weB LOG, vlog, comes from video web LOG" (Safko 2012, p.225).

Media sharing goes back to the 90s when the first short videos were uploaded on IFILM.net Back then many users had dial-up connections, which made watching videos a slow process. Today, mostly all users have the required software to watch videos immediately, without downloading special streaming video players' upfront (Hilker 2010, p. 42).

When discussing media sharing, so called *tags* are indispensable. Tags are used to search content that is not textual. "Tags are nonhierarchical, meaning they are not organized into a parent-child tree structure, and they are created by users rather than being determined by the site owner." (Zarella 2012, p.81) Whenever a first tag is set, the category is created into all tags which will fall under the term. In order to tag, Zarella (2012) describes the handlings as follows: It is better to tag too much than too few. When there is doubt, add more. To tag specific pieces of media the user can tag multiple words. The best way to start is to do "pyramid thinking". Starting with the most specific frames, going down to single words, such as categorical words (what is seen in the background, what the video / picture deals with). Any kind of content related relevant word helps to make the tag worth it for users (Heymann-Reder 2011, p. 198). The most common media sharing sites are YouTube, Flickr and SlideShare (Hilker 2010, p. 49).

2.2 Ratings and Reviews

Once the customers are talking about brands, products or services of a company, the company/ brand needs to have an online presence as well. Especially local businesses should have a presence and registration on local review sites. At this stage it is important to differentiate between users who are into socializing and review-site visitors. While the socializing users are simply having fun, the review-site user is in the midst of making a buying decision. This stage is important to companies as they have to be there where the visitor and potential customer is searching for them. For instance a person who is looking for a dentist is not willing to amuse her- or himself for medical help (Zarella 2012, p. 131). Rating and review sites are the most cost-effective marketing a company can do. This is a special online advertising form, which requires a low investment of time and money in terms of cost -effectiveness.

Many rating and review sites are for free and allow every user to post anonymously. Most of these sites have incorporated a reputation system, which enables the users to scale the usefulness and accuracy (Blanchard 2011, p. 239). For marketers, ratings and review sites have a high relevance – especially for those with local business focus. In order to find a business or service, the users go online on listings and start searching. Usually the findings are ranked (by relevance and the number of reviews). In order to be found by users, the company/ business should use words and phrases that people may search for. With regards to the reviews, some companies are looking for so called *sock puppets*. This means that there are business owners who set up faked accounts to increase the reviews of the business. Additionally, there are owners who pay people to post positive reviews on the business. As this is a very bad form, review sites have already started to implement algorithms designed to spot fraudulent activity. Chances to get caught are high and worse for all parties involved (Zarella 2012, p. 135).

Many review sites have a feature which allows responding to a post / review. If companies respond to reviews the action has to be taken and treated deliberately. Responses from customers are subjective and their perception of the business which cannot be wrong. There is only one chance to get this respond and issue fixed. The company has to check with the user if there is a way to get it done properly. Also, the company has to keep in mind that the response will be there for the entire web to read – probably for a long time (Sterne 2011, p. 199).

2.3 Measurement

Measurement is an important topic to be taken into account in the social media business as well. "A social media program, in order to be effective, needs to be measureable within the context of the business it serves: measurable, in other words, against the very objectives and targets it aims to influence." (Brito 2011, p. 194.)

Measurement is fundamental as it allows an adequate measurement practice in place, success, progress, and even failure along the entire life cycle (Roskos 2012, p. 41). It is relevant to understand what works and what doesn't. It allows the top management to make adjustments on the fly. Furthermore it enables organizations to justify investments (especially those for social media activities) over time as they are able to effectively measure the investments value to the organization (Brito 2011, p. 194).

There are several units how to measure. One possibility is a *metric* (Sterne 2010, p. 39). Following Zarella (2012, p. 207), there are two metrics for social media marketing: on-site and off-site.
On-site metrics are measuring activities which take place directly on the website / homepage. The most common and important thing to measure is the return on investment (ROI). This means the marketer gets an impression how much money the efforts are contributing to the business (Kremer 2012, p. 75). Zarella states that all analytics packages allow tracking certain actions on a side, no matter if they are purchases or the completion of lead form.

Lead-based companies are asked to estimate how much a lead is worth by calculating what percentage of leads turn into business, and finally what an average customer is worth to the company. There are several softwares, which allows companies to configure their tracking mechanism to include the actual price of sale or the value per lead. This enables the organization to assign a monetary figure to each source of social media traffic (Heymann-Reder 2011, p. 94). Besides, there are some analytic systems allowing the integration of the internal sales system to implement a so-called *closed loop marketing* concept. The closed loop marketing concepts allow attributing closed business to specific leads, traffic sources and campaigns.

In order to calculate the actual ROI, the costs of social media work (includes also time and monetary investments) needs to be deducted from the generated income. The result should be a positive number in order to have a profitable investment. If the numbers are negative, the campaigns have to be re-visit (Heymann-Reder 2011, p. 93). While analyzing the figures, it is important to pay attention which sites and tactics are generating the most value. According to Zarella (2012, p. 209), a company should focus on the types that work for a company. Due to the fact that not all visitors from a social media outlet are turning into customers or leads directly, a company should also indeed measure metrics that indicate how *engaged* people are. Two easy engagement metrics are time on-site and page views per visit. Another important metric is the *bounce rate*. Bounce rates allow companies to identify which pages or sources or traffic are inefficient. According to Zarella (2012, p. 211) a bounce is defined if a visitor visits a page and does not go to any additional page afterwards – the customer bounced right on the side. If there are high numbers of bounces on a site, it is required to check which part of the site the people are landing to strengthen the relevance of the site.

Off-site metrics are measuring activities that happen on other sites where companies, customers and consumers interact. This off-site metrics occur in other places than the own site. One of the most common one is Twitter and its obvious metric is the number of people following. This represents the potential reaches and shows the possible followers but it is highly recommended not to stay only with this metric. As described in chapter microblogging, it is possible to get followers by simply following a ton of people and wait for them to follow back. But this measure is too little to state how engaged followers are with the tweets (Zarella 2012, p. 213).

Basically, social media cannot be seen as a stand-alone approach which easily enables companies to identify the exact (social media) measurements. Usually there are certain online and offline marketing activities which influence the entire actions. As a result, all activities require each other.

3 Summary

Social Media is a very complex topic. With regards to the changing environments and fast moving online Web 2.0 conditions, companies need to face social media activities increasingly.
Within this research paper only some of the basic tools were introduced. It needs to be taken into account that there a much more tools.

It is highly recommended to face all corresponding influence factors in order to avoid a poor performance and implementation. Basically social media and its implementation has to be treated carefully since not all tools and approaches are feasible for all small and medium sized companies.

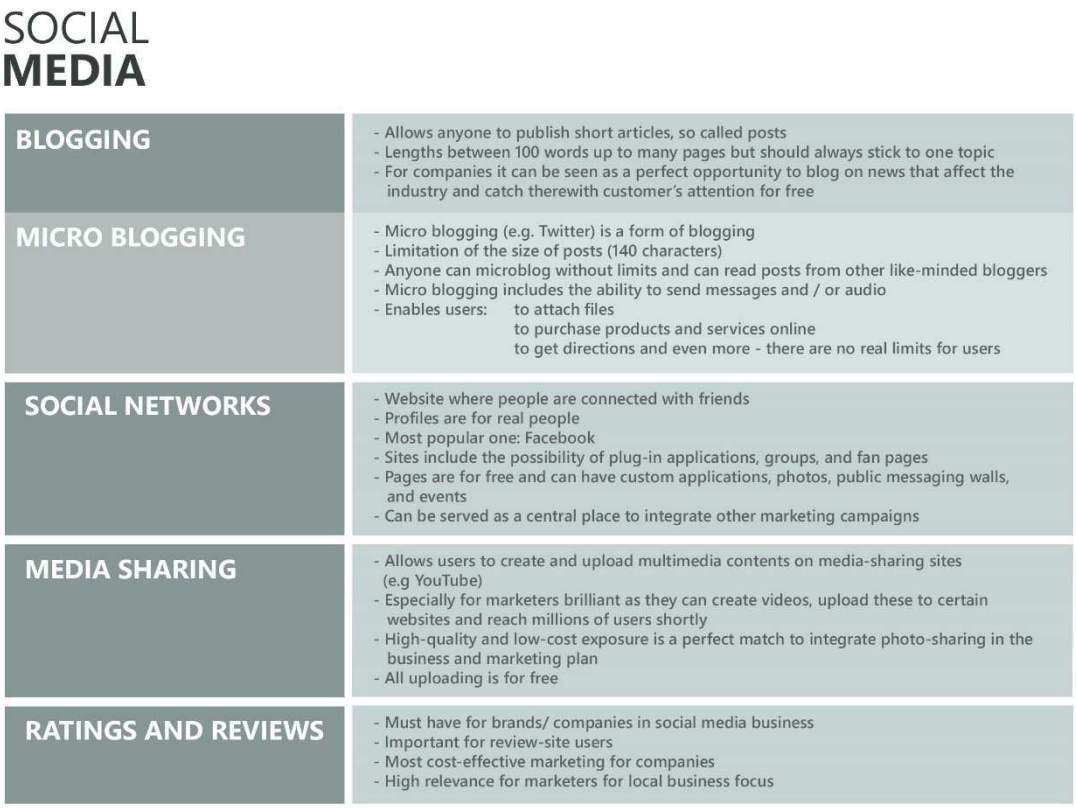

Figure 2: Comparison of social media tools

Source: Own illustration

Figure 2 illustrates the overview of all tools discussed and describes the possible uses and applications.

Concluding, it needs to be mentioned, due to the given frame and the focus set within the paper, the man power aspect was not considered. In order to implement social media into companies, the entire man power caused by social media needs to be discussed and re-thought. Social media requires expert knowledge and a strong personnel structure within the marketing department.

A Theoretical Framework on Factors Affecting Entry Mode Choices of MNCs

Shahzia Khan, Assistant Professor Dubai, United Arab Emirates

Email: shahzia_khan@manipaldubai.com

Abstract

All the multinationals have to confront a critical situation of choosing from the various modes of entering a foreign country. Deciding the right entry mode is the first step of the success ladder of the MNCs. A wrong entry mode choice can cannibalize the entire business operation. The purpose of this paper is to explore the factors that influence the firm's choice of entry mode strategy. The study relies on secondary data, the data for which was obtained from numerous journals (both online and print). Nuances of significant determinants that were likely to influence the entry mode choice of the MNCs were studied.

Keywords: Entry Mode Choice, MNC, FDI, Globalization

1. Introduction

All the multinationals have to confront a critical situation of choosing from the various modes of entering a foreign country. There has been an extensive amount of research around the area of entry modes and what affects the MNC's entry mode choice. Kumar and Subramaniam (1997), Chung and Enderwick (2001), as well as Nakos and Brouthers (2002) emphasized that the choice of market entry mode is a critical strategic decision for firms intending to conduct business overseas. "The mode of entry is the fundamental decision a firm makes when it enters a new market because the choice of entry automatically constrains the marketing and production strategy of the firm." (Johnson & Tellis, 2008). One way of viewing the entry mode alternatives is to view them as either equity modes or non-equity modes. Equity based modes include wholly owned operations and equity joint ventures; while non-equity based modes include contractual agreements and export (Ozlati & Abrami, 2008). "Equity modes differ dramatically from non-equity modes in resource commitment, risk, return, control, and other characteristics"(Pan & Tse, 2000). There are number of factors that influence the firm's choice of entry mode strategy and its functioning in the host country. Some are related to the general business environment of the host country, the nature of product/service, company related factors, competitiveness of the indigenous firm's, host country production factors and so on.

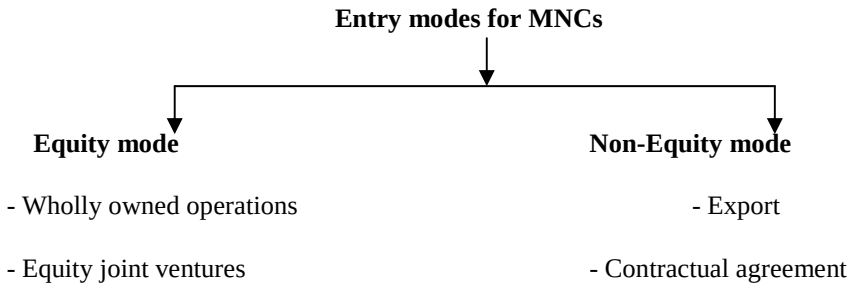

Fig 1. Equity & Non- Equity Entry Modes

2. Research Methodology

The purpose of this paper is to explore the determinants that influence the firm's choice of entry mode strategy. The study relies on secondary research, the data for which was obtained from numerous

journals (both online and print). Nuances of significant determinants that were likely to influence the entry mode choice of the MNCs were studied.

3. Factors Affecting Entry Mode Choices of MNC

The various factors and their influence on the foreign market entry mode decision are studied separately to explore their impact on the entry mode choices on MNCs.

3.1. Cultural Distance

Cultural distance refers to the difference between the cultural parameters of two nations. The literature review revealed a dichotomous opinion about the culture distance and firm's choice of entry mode. As per one view higher is the cultural distance, higher is the control required to mitigate the transaction costs and as a result the firm has to choose a high equity mode to enter the foreign country (Hennart & Reddy, 1997; and Li & Guisinger, 1992). Brouthers and Brouthers (2003) have stated that the firms may select wholly owned entry modes in countries that depict a larger cultural distance. Barkema et al (1997), and Anderson and Gatignon (1986) on contrary are of the view that higher cultural distance is associated with higher risk; hence, equity modes with lesser degree of control should be preferred. Hsieh and Shen (2003) explored that in Asia, with a greater cultural distance, banks tend to establish low control entry modes to avoid uncertainty in the region. However, Ozalti and Abrami (2008) in their study have found that cultural distance doesn't seem to affect the entry mode decision of Swedish companies in United Arab Emirates (U.A.E) to great extent.

3.2 Political Risk

Hill (2007) defines political risk as a change in the political regime that result in enactment of laws that are less favorable to international business. Political risks are critical determinant of FDI (Chan and Gemayel, 2004). Dow and Karunaratna (2006) argued that, the dissimilarities in the political systems increase the cost and uncertainty of business – government communication channels. Loree and Guisinger (1995) in their study on the influence of political institutions on US FDI have explored a positive relation between equity FDI and political stability. Kinoshita and Campos (2002) have also empirically supported that countries with political stability attract more FDI. Moreover a similarity in the political system of two nations also favors higher equity modes Flores and Aguilera (2007).

3.3. Economic Risk

International Business is susceptible to both the external and internal economic condition of the country. "A host government's political situation or desires may lead it to impose economic regulations." Czinkota, Ronkainen and Moffett (2003). Chan and Gemayel (2004) considered economic risk to be an important determinant of FDI. If MNC poses an economic risk in a nation, it avoids opting for high equity modes of entry to mitigate such risks. Dealing with country that is not close in economic distance could prove to be risky. According to empirical finding of a study conducted by Johnson and Tellis (2008) on success for market entry into china and India, the success is attributed to economic similarity.

3.4. Legal risk

The firms have to take the legal stability of the host country into account while choosing foreign entry mode. The empirical findings of the study conducted by Ozlati and Abrami (2008) indicated that the Swedish firms that consider legal risk important in UAE prefer joint venture (LLC) mode of entry. Globerman and Shapiro (2003) stated that, "countries whose legal systems are rooted in English common laws are more likely to be recipient of US FDI flows."

3.5. Currency risk

Currency risk is a risk that stems from the change in the price of one currency against the other. This leads to both transaction risk (a risk of unfavorable fluctuation of exchange rates) and translation risk (accounting risk). The fluctuation in the currency impacts the international business dramatically. Notwithstanding the importance of assessing currency risk, Zhao and Decker (2004) found that currency risk doesn't seem to be affecting the choice of entry mode of Swedish companies in UAE.

3.6 Natural resources

Chen (1996) argued that natural resources of the host country play in important role in magnetizing FDI in that region. In other words, while making a choice of foreign entry modes, a firm opts for equity modes in a country blessed with adequate natural resources in order to benefit from it. Bhaumik and Gelb (2003) have found that in South Africa the entry mode choice significantly depends on the fact whether or not the country is resource seeking. Notwithstanding these studies, Lu, Brennam, Chang and Luo (2008) explores that presence of natural resources is not sufficient to attract FDI in Inland areas of China.

3.7 Labor cost and Quality

It is believed that lower labor cost in the host country is likely to attract more FDI as MNCs gain from the reduced labor cost abroad (Kinoshita & Campos, 2004). "Labor are effective in the choice of Istanbul over the other cities within Turkey" (Berkoz and Turk, 2005). Opposing these studies are the studies conducted by Wei el al (1999); Fu (2000); and Lu, Brenan and Luo (2008) that indicated a negative correlation between effective wage and FDI. Advocating the importance of labor quality, Lu, et al. (2008) state that " MNCs choose location that are capable of supporting high-valued activities rather than production sites that have abundant low –cost laborers".

3.8. Industrial agglomeration

Empirical study by Kinoshita and Campos (2002) revealed that industrial agglomeration in a region is the main determinant of attracting FDI. Consistent with their study was empirical finding of Lu, Brennan and Luo (2008) that indicated industrial agglomeration to be an important factor for FDI invested in China's inland area as MNCs largely benefit from it. In metropolitan areas in Turkey, industrial agglomeration was not considered to be an important determinant of FDI (Berkoz & Turk, 2005).

3.9 Market attractiveness

Market attractiveness is size, present wealth, future wealth and other such attributes of a market. An increase in the market size will lead to an increase in the demand that will drive more direct investment in the country (Chakrabarti, 2003). Moreover, empirical study on FDI location choice in China's Inland area depicted a 'market- seeking nature' (Lu, Brennan and Luo , 2008). Kwon and Konopa (1992) also have significantly found that size of the market is one of the significant factors that determine the firm's likelihood to choose higher equity mode entries.

3. 10. Infrastructure

Certain studies indicate that physical infrastructure influences the MNCs' decision to enter the region due to expected cost of operation in a particular host country (Root and Ahmed, 1978; Loree and Guisinger ,1995 ;and Berkoz and Turk,2005) . A positive relationship between infrastructure and inward FDI was observed in various studies conducted by Wei and et al. (1999) , Mariotti and Pischitello (1995). If better and quality infrastructure will be present in the host country, the firm will prefer choosing higher equity modes like FDI over exports in those region .

3.11. Host Government ownership restriction

Bhaumik and Gelb (2003) have explored that in Egypt, the entry mode choice significantly depends on the government attitude towards foreign investor and extent of liberalization of FDI regulation. Agarwal and Ramaswami (1992) suggested that if host government ownership restrictions are found in a country, a firm prefers non- equity mode. Kinoshita and Campos (2002) also stated that more liberalized is the country towards external trade, more FDI it will attract. Ozlati and Abrami (2008) in their study found that government ownership do influence the choice of entry mode, their study indicated that owing to the government ownership restriction, Swedish firms in UAE opt for wholly owned firms (free zones) as opposed to joint ventures which were indicated in the previous researches.

3.12. Control

Control refers to the firm's ability to influence system, take decisions and monitor the method to operate that collectively impacts the future growth and prospects of the firm. A firm while making a choice of entry mode considers the degree of control it can receive by resorting to that particular mode of foreign entry. Johnson and Tellis (2008) have advocated the choice of an entry mode that renders the firm highest degree of control. Empirical study conducted by Ozlati and Abrami (2008) also provided enough evidence that Swedish firms in UAE used higher equity modes like free zones (wholly owned firm) to establish high control.

3.13. Competitiveness of indigenous firms

Competitiveness of indigenous firm is attributed to the product differentiation, product quality, brand name, control of distribution channels, corporate size and many more factors. If the firm entering in a foreign market does not witness a competitive advantage over the local firm, it prefers either not entering the market or opts for lower equity modes Caves (1974). Contradicting to this, Kwon and Konopa (1992) empirically found that firms choose higher equity modes like FDIs that provide them with greater access to foreign market when local firms' competitiveness is high.

3.14. Nature of industry

Nature of industry also influences the entry mode decision of a firm. Ghahroudi (2009) has found that Japanese MNCs in India prefer to acquire high level of equity ownership especially when subsidiary is in the manufacturing industry.

Provided below is the table (refer table 1) that summarizes the different factors and their impact on the entry mode choice of the multinational companies.

4. Conclusion

One of the key decisions that a firm has to take when it decides to operate in a foreign land is choosing the ideal entry mode strategy. The mode of entry impacts the vital strategies of the firm in the nation that it decides to function. The business environment of the host country and the policy of the entering firm collectively affect the entry mode choice. The study revealed that nuances of factors like cultural distance between the region, political risk, economic risk, legal risk, currency risk involved, presence of natural resources, the cost and quality of labor in the foreign land, the industrial agglomeration, lucrativeness of the foreign market, the prevailing infrastructure, the host government ownership restriction, the company's need to control, the competitiveness of indigenous firms, and the nature of industry are likely to influence the entry mode decision. However, these factors impact different multinationals entering different foreign locations differently. An empirical study should be conducted to understand how strongly these factors would influence various MNCs while entering a particular foreign region.

Table 1: Summarized Findings on the Factors Influencing Foreign Entry Mode Decision

S.No.	Factors Studied	Finding	Authors
1	Cultural Distance	Higher cultural distance results in higher equity modes	Hennart and Reddy(1997)
			Brouthers and Brouthers (2003)
			Li and Guisinger (1992)
		Higher cultural distance results in lower equity mode	Barkema et al(1997)
			Barkema and Verneulen (1998)
			Hsieh and Shen (2003)
			Flores and Aguilera (2007)
			Tihanji, Griffith and Russell (2005)
			Esperanca and Gulamhussen (2001)
			Quer, Claver and Rienda (2007)
		Higher cultural distance reduce the success rate of MNC in host country	Johnson and Tellis (2008)
		Cultural distance does not affect the entry mode choice	Ozalti and Abrami (2008
2	Political Risk	Critical determinant of FDI	Chan and Gemayel (2008)
			Sundaram and Black (1999)
		Political risk increases the uncertainty of business	Dow and Karunaratna (2006)
		Political closeness increases the likelihood o higher mode of entry	Loree and Guisinger (1995)
			Kinoshita and Campos (2002)
			Flores and Aguilera (2007)
3	Economic Risk	Important determinant of FDI	Chan and Gemayel (2008)
		Economic similarity results in success	Johnson and Tellis (2008)
4	Legal risk	Firm prefer joint venture in case of high lega risk	Ozlati and Abrami (2008
		Legal similarity attracts more FDI	Globerman and Shapiro (2003)
5	Currency risk	Currency risk has the lowest effect on the choice of entry mode.	Ozlati and Abrami (2008
6	Natural resources	Presence of natural resources attract FDI	Chen (1996)
		Entry mode decision in South Africa is resource-seeking	Bhaumik and Gelb (2003)
		Natural resource is not sufficient to attract FDI	Lu,Brennam, Chang and Luo (2008)
7	Labor cost	Effective labor wage attract higher mode like FDI	Kumar (1994)
			Berkoz and Turk (2005)
			Cheng (2006)

			Kinoshita and Campos(2004)
		Negative correlation between effective wage and FDI	Wei el al (1999)
			Fu (2000)
			Lu,Brennam, Chang and Luo (2008)
		US MNCs choose foreign location with higher wages	Flores and Aguilera (2007)
		Effective wage don't effect the choice	Ondrich and Wasylenko (1993)
		MNCs value high-quality activities rather lower wages	Lu, Brenan , Chang and Luo (2008)
8	Industrial Agglomeration	Main determinant of FDI	Kinoshita and Campos (2002)
			Lu,Brennam, Chang and Luo (2008)
			He (2003)
			Berkoz, L., and Turk, S.S.(2005)
9	Market Attractiveness	Positive relationship between market size and FDI	Chakrabarti (2003)
			Contractor (1991)
			Loree and Guisinger (1995)
			Wenget (1995)
			Lu,Brennam, Chang and Luo (2008)
			Kwon and Konopa (1992)
			Flores and Aguilera (2007)
		Market size in no longer a determinant of FD	Kinoshita and Campos (2002)
10	Infrastructure	Better infrastructure attract higher equity modes	Wei and et al. (1999)
			Mariotti and Pischitello (1995)
		Infrastructure influences entry decision of firm	Root and Ahmed (1978)
			Loree and Guisinger (1995)
			Berkoz and Turk (2005
11	Host Government ownership restriction	Presence of host Government ownership restriction results in choice of low equity mode	Agarwal and Ramaswam (1992)
			Kwon and Kanopa (1993
			Kinoshita and Campos (2002)
			Yin and Makino (2002)
		Entry mode choice in Egypt depends on liberalization of FDI	Bhaumik and Gelb (2003)
		`Firm choose high equity mode in the presence government ownership restrictions	Ozlati and Abrami (2008
12	Control	Firms should choose the modes that render them higher degree of control	Johnson and Tellis (2008)
		Control is an important determinant of entry	Ozlati and Abrami (2008

		choice in UAE	
13	Competitiveness of Indigenous firm	When competitiveness of local firms is high, lower equity modes should be preferred.	Caves (1974)
		Higher equity modes should be preferred when competitiveness of local firm is high.	Kwon and Konopa (1992)
14	Nature of Industry	Japanese manufacturing industry prefer high equity mode in India	Ghahroudi (2009)
		The extent to which it sources tangible resources from the local partner is an important determinant for service sector in Egypt and the extent of liberalization of loca industry is important entry mode determinan for manufacturing firms	Bhaumik and Gelb (2003)

Abstract

Standardization verses adaptation of marketing strategies has always been in question and is considered to be one of the most sensitive and ambiguous issues for many MNCs. The standardization school of thought believes that the world market is becoming a homogeneous place and standardized approach can generate numerous advantages. Contradicting the standardization school of thought, the believers of adaptation approach argue that the differences across boundaries stimulate the MNCs to customize their business strategies to meet successfully the requirements of the host country. It may become imperative for the MNCs to respond to the national differences. What is equally debatable is the degree of adaptation or standardization of each element of marketing- mix (product, price, place and promotion). The purpose of this study is to gauge the level of standardization or customization practiced by the Fast Moving Consumer Goods (FMCG) MNCs while marketing their products in the UAE. The results of the study revealed that the FMCG MNCs in UAE neither pursued a pure standardization nor a pure customization as a single approach to market their product in the UAE instead they prefer to implement a mixed strategy.

Keywords: Standardization, Adaptation, Marketing-mix, Globalization, International Marketing, Fast Moving Consumer Goods (FMCG)

1. Introduction

International marketing has always depicted a dichotomized approach. One approach argues that owing to the technology, modern communication, travel and transport world is becoming more homogeneous which demands company to market the same product in the same fashion across the globe (standardization) (Levitt, 1983). The other approach focuses on customizing the product and the related strategies to meet heterogeneous market requirement (Adaptation). Standardization (globalization) verses adaptation (customization) of business practices has always been in question and is the most sensitive, debatable and ambiguous issue for many MNCs. International marketers have a more challenging and complex strategic decision-making related to the marketing – mix than their domestic counterparts (Wall & Rees, 2004). Moreover, to what degree should these marketing-mix elements (product, price, place and promotion) be adapted or standardized is a debatable topic.

Standardization involves offering the identical product lines at identical prices through identical distribution channel, supported by identical promotional programs in several countries (Deirdre, 1999). The standardization school of thought believes that the world market is becoming a homogeneous place and standardized approach can generate advantages through economies of scale and greater efficiencies (Kogut, 1985 and Levitt, 1983). Supporting the standardization approach, Levitt (1983) argued, "World's needs and desires have been irrevocably homogenized and that this makes the multinational corporation obsolete and the global corporation absolute." Czinkota , Ronkainen and Michael (2003) mentioned that economies in product R&D, marketing, economies of scale, control of marketing programs and "shrinking" of world market place are the factors encouraging standardization. Ball and McCulloch (1999) stated that the standardization of the

marketing- mix benefits the management from the lower costs, easier control and coordination from head quarter and reduction of the time consumed in preparing the marketing plan.

Contradicting the standardization school of thought, the believers of adaptation approach argue that the differences across boundaries in terms of social, cultural, economical, political, technological, legal and other environmental factors stimulates the MNCs to customize their business strategies to meet successfully the requirements of the host country (Bartlett & Ghoshal, 1987; Boddewyn et al,1986). The empirical findings, of the study conducted by Samiee and Roth (1992) on influence of global marketing standardization on performance, did not support superior performance resulting from global standardization. They further stated that the fact that Coca – Cola and Colgate-Palmolive sell some of their products in more than 160 countries does not signifies that they have adopted a high degree of standardization for all their products globally. Ball and McCulloch (2004) argued that notwithstanding the advantages of standardization, many firms depending upon the product type, the environmental forces, and the degree of market penetration find it necessary to either modify the present mix or develop a new one while going international. Czinkota, Ronkainen and Moffet (2003) were also of the opinion that differing use conditions, government and regulatory influences, differing in buyer patterns, local initiative and motivation in implementation, adherence to the marketing concept; together encourage the MNC to embrace the adaptation approach.

Besides the issue to standardize or adapt, the degree to which international strategies should be standardized is the concern of recent times (Samiee & Roth, 1992). According to Hodgetts and Luthans (2003) while going global, the MNCs should respond to the national differences. Czinkota, Ronkainen and Michael (2003) advocated that ideally the international marketers should neither pursue an extreme standardization nor extreme customization instead they should think globally and act locally. Global thinking calls for flexibility in exploiting good ideas and products on worldwide basis regardless of their origin.

2. Literature review

In order to satisfy the customers, marketers have to devise integrated marketing program to create, communicate and deliver value to the customers (Kotler & Keller , 2006). McCarthy (1996) classified the various tools required to meet the marketing objectives into the four Ps i.e. product, price, place and promotion that are considered to be critical tool of every domestic and international marketer. While going international numerous factors like the market position, market condition, market environment, product characteristics and organizational factors collectively tend to influence the standardization and adaptation of marketing-mix Hou (2001). The implication of each of the elements of marketing-mix in international marketing is discussed below with special focus on the degree to which it should be adapted or standardized.

2.1. Standardization or Adaptation of Product Strategy

It is advantageous for MNC to standardize the brand name of the product as it allows the firms to reduce the production, packaging, design and advertising costs (Peerally,2008). Richer (1999) empirically found that the German companies tend to standardize their product element of the marketing mix to the highest degree. Despite the success of the product in the home country, certain environmental differences in the host country such as level of literacy, income, technical skills of potential customers, climatic conditions, power level , availability and quality of maintenance support , and many such factors can often force the company to make unexpected or costly changes (Jeannet & Hennessey, 2004). Packaging is one of the elements of marketing-mix that is generally modified by the company.

Peerally (2008) stated that the legal rules and regulations of the host countries influence the labeling and health requirement, and the cultural forces impact the language used on the labels or ingredients and consciousness of consumers. Keegan (2002) advocated that the compliance of product labeling and instruction with the national laws and regulation, and the language of that country. Delaney (2001) stated that in United States a slick black package with imprinted gold and silver is considered

to be elegant but the same package in Africa suggest death. Huo (2001) found that in due to legal and political factors in China, it is imperative for the foreign products to translate the instructions in Chinese; hence Shiseido products had to translate the instructions into Chinese to market them in China.

2.2. Standardization or Adaptation of Pricing Strategy

Standardization of the pricing strategy has the lowest potential as compared to the other elements of the marketing-mix (Shoham, 1995). Birnik and Bowman (2007) while referring to the various studies conducted by Boddewyn and Grosse (1995); Chhabra (1996); Grosse and Zinn (1990); Mitchell at al.(1998); Ozsomer et al. (1991); Sorenson and Wiechmann (1975); Vrontis and Papapsolomou (2005); Zou at al(1997) bolstered the fact that pricing strategy happens to the least or one of the least standardized elements of the marketing mix . Shaw and Ritcher (1999) empirically found that German companies tend to adapt the pricing strategies in the foreign company but the British companies, on the contrary, tend to standardize their pricing strategy the most in the international market. Huo (2001) found that Shiseido had to adapt the price of the products in China and U.K. due to the difference in the tax and tariff system.

2.3. Standardization or Adaptation of Distribution (Place) Strategy

Rodrigues (2001) stated that distribution methods generally require variations from country to country as well as within each country as the methods are shaped by the size of the market, the scope and quality of the competition, by the available distribution channels, and by the firm's resources. Distribution strategy of the MNCs usually embraces the adaptation approach in the host country.

Birnik and Bowman (2007) in their study collected enough evidence from the prior researches conducted by Boddewyn and Grosse, 1995; Chabbra, 1996; Michell et al., 1998; Ozsomer et al. 1991; Sorenson and Wiechmann 1975; Vrontis and papsolomou, 2005; Yip, 1997; and Zou et al. 1997 that sales and distribution strategy of the MNCs tend to show fairly low level of standardization but typically not as low as pricing. Huo (2001) also found a moderate adaptation rate of distribution strategy of Shiseido product in both China and U.K.

2.4. Standardization or Adaptation of Promotion Strategy

There is an ongoing debate on whether the MNCs should standardize or adapt their promotion / advertising strategy. Dichotomous approaches have been found from the past studies that indicate that British companies tend to adapt their promotional activities (Shaw & Ritcher ,1999) whereas Huo (2001) found that Shiseido Company while marketing its product to China and UK tend to keep the promotion strategy standardize in both the countries. The question arises- which approach is more effective and should be embraced by the marketer, and what are the factors that lead to the adaptation and standardization of the promotion strategy? In general problems related to international promotion strategy include the legal aspects of the country, tax considerations, language complexities, cultural diversity, media limitations, credibility of advertising, and degree of illiteracy (Rodrigues,2001). The standardized advertising is recommended when the economic, technological, legal, social, and cultural environment of the host country is found to be at par with the home country; if these environmental factors depict heterogeneity instead of homogeneity then an adapted advertising strategy should be embraced. Bolstering the adaptation strategy, Luqmani et al. (1987) suggested that advertisement in Saudi Arabia should be designed in such a fashion that it is compatible with the religious norms, socio- economic environment and the government priorities. Chandra, Griffith and Ryan (2002) argued that in order to meet the needs of international target market it become essential for the marketer to adapt the advertisement theme, slogan, idiomatic expressions, symbols and colors.

Gaurav (2008) like Melewar and Vermmervik (2004) advocated that the contingency approach towards advertising is the most acceptable approach, rather than pure standardization or adaptation, as it not only identifies the local preferences but also facilitates some degree of standardization.

3. The Research Methodology and Objectives.

This study was primarily conducted to study the degree of standardization and customization pursued by each element of the marketing –mix (product, price, place and promotion) to deal with the varying demand of the consumers and the overall business environment.

For the purpose of this study a blend of both the qualitative and the quantitative approach has been used. To carry out this study literature was reviewed, objectives were set, and questionnaire was designed to gather data to meet the objective of the study. The questionnaire was sent out to hundred different Fast Moving Consumer Goods (FMCG) MNCs in the UAE. However, only fifty-three companies responded and participated in the survey. Hence, the response rate was merely fifty three per cent.

The data gathered through the questionnaire was systematically analyzed and interpreted to achieve the desired objectives of the research. Descriptive analysis was carried out using the mean, frequency, standard deviation, variance and the coefficient of variation. The findings were presented in the form of table. SPSS 16.00 was used for a smooth and accurate analysis. Inferences were drawn by overall analysis of the various responses and the results of the analysis were then methodically juxtaposed to draw an effective conclusion about the objectives of the research study.

4. Results and Analysis

To meet the objective of the study, the respondents (FMCG MNCs) were asked to rate the key elements of the marketing-mix strategy (product, price, place and promotion) pursued in UAE on the basis of the level of standardization practiced in the region as compared to the marketing practices in their respective home country. This was done to gauge the level of standardization or customization followed by the foreign MNCs while marketing their products in the UAE. The findings are presented in the form of the table provided below (refer table 1).

It can be inferred from the table that of all the various elements of the marketing mix (four Ps), the brand name (*M*= 4.7, *SD*=0.54) is standardized the most followed by the standardization of the product quality (*M*=4.11, *SD*= 0.58) and the advertising message (*M*= 3.77, *SD*= 0.51). This can be associated with the fact that keeping pace with the globalization, the MNCs tend to establish a consistency of these strategies to build a uniform brand image in the minds of the consumers across the globe. However, due to the socio- economic, cultural and legal difference, also and owing to the varying customer's taste and preferences the foreign firms have to customize the other element. The analysis revealed that the foreign company standardizes few elements while the others are customized to align to the differences that prevail between two regions. Amongst the ones that are highly customized include the price of the product (*M*= 2.02, *SD*= 0.69), personal selling techniques (*M*=1.96, *SD*=0.65) and the discount structure (*M*=1.94, *SD*=0.63).

The findings indicate that of all the elements of the marketing mix, the FMCG MNCs customize their pricing strategy the most (average of mean being 2.36 and average of sum being 125.33). The customization of the pricing strategy is consistent with the studies of Czinkota et al. (2003), Shoham (1995), Boddewyn and Grosse (1995),Chhabra (1996),Grosse and Zinn (1990), Mitchell at al.(1998),Ozsomer et al. (1991), Sorenson and Wiechmann (1975),Vrontis and Papapsolomou (2005), Zou at al. (1997),Shaw and Ritcher (1999), and Huo (2001).

At the second place, FMCG MNCs customize the promotion strategy (average of mean being 2.69 and average of sum being 139.57). The MNCs need to adapt to the differing business environment of the region and have to address the legal, social, economic, demographic and cultural differences that prevail in the region while formulating the advertising and promotional strategies. This supports the studies conducted by Chandra, Griffith and Ryan (2002), Shaw & Ritcher (1999),Luqmani and Yavas (1987) that insisted on the adaptation of the promotional strategies by the MNCs.

Following promotion strategy, the distribution strategy (*M*= 2.79 , *SD*= 0.66) is pursued in the region is adapted the next. It can be inferred that owing to the fact that the market size, prevailing competition, infrastructure and the available distribution channel across countries varies, this results in the adaptation of the distribution strategy in the foreign land. The finding of the study is consistent with the previous findings of Birnik and Bowman (2007), Rodrigues (2001), Boddewyn and Grosse, 1995; Chabbra, 1996; Michell et al., 1998; Ozsomer et al. 1991; Sorenson and Wiechmann 1975; Vrontis and papsolomou, 2005; Yip, 1997; Zinn and Grosse, 1990 ; and Zou et al. 1997, and Huo (2001).

The element of marketing- mix that is attributed to the lesser degree of adaptation as compared to price, promotion and distribution strategy is the product strategy (average of mean is 3.50 and the average of the sum is 185.5). While some elements of the product strategy like the brand name and the quality are kept standardized, the other elements like packaging and labeling calls for customization. Hence, the MNCs are required to follow a blend of both standardization and customization while formulating the pricing strategy. Cherunilam, (2007), Jeannet & Hennessey (2004), Czinkota, Ronkainen & Moffett (2003), Hou (2001), and Shaw and Ritcher (1999) were of the opinion that the product strategies could be slightly customized due to the changes in the market conditions.

As evident from the table 1 the FMCG MNCs neither follow pure standardization nor pure customization as a single approach to market their product in the UAE. It needs to embrace a mixed strategy of pursuing both the standardization and customization to bridge the gap in the region.

Table 1: Standardization of the Various Elements of the Marketing Mix Strategy

Marketing Mix	Elements of Marketing Mix	Mean	Std. Deviation	Variance	Coefficient of Variation	Range	Minimum	Maximum	Sum	Ranking
Product Strategy	Brand name	4.7	0.54	0.29	11.49	2	3	5	249	1
	Product Design & Features	3.47	0.82	0.68	23.72	3	2	5	184	4
	Product Quality	4.11	0.58	0.33	14.04	3	2	5	218	2
	Product Ingredients	3.3	0.99	0.98	30.06	3	2	5	175	5
	Packaging	3.09	0.6	0.36	19.32	3	2	5	164	8
	Language on the label	2.32	0.61	0.38	26.42	2	2	4	123	11
Pricing Strategy	Pricing Approach & Strategy	3.13	0.74	0.54	23.48	3	2	5	166	7
	Price of the Product	2.02	0.69	0.48	34.31	2	1	3	107	15
	Discount Structure	1.94	0.63	0.4	32.63	2	1	3	103	17
Distribution Strategy	Distribution Channel Followed	2.79	0.66	0.44	23.69	3	2	5	148	10
Promotion Strategy	Advertising Message	3.77	0.51	0.26	13.4	3	2	5	200	3
	Advertisement Appeal	2.94	0.57	0.324	19.35	3	2	5	156	9
	Media Used	3.28	0.6	0.36	18.32	3	2	5	174	6
	Sales Promotion Techniques	2.19	0.65	0.42	29.77	3	1	4	116	12
	Direct Marketing	2.13	0.81	0.66	38.03	3	1	4	113	14
	Public Relation Strategy	2.15	0.72	0.52	33.4	3	1	4	114	13
	Personal Selling	1.96	0.65	0.422	33.11	3	1	4	104	16

5. Conclusion

The study revealed that the FMCG MNCs in UAE adopted a combination strategy that incorporated both the attributes of standardization and adaptation. Some strategies where standardized while others were customized. The pricing strategy is customized the most followed by the adaptation of the promotion and the distribution strategy. The product strategy showcased the least degree of adaptation. Among all the elements of the product strategy the brand name is standardized the most to ensure easy acceptance of the product in UAE and to ensure a consistency of brand image. The language on the label is customized the most due to UAE rule of practicing bilingualism; both Arabic and English language is used on the label. Of all the elements of the pricing discount structure is customized the most strategy due to the differences in the competition and the market structure.

The research has focused on two important approaches: degree of standardization and customization of marketing strategies. The study was conducted only on the FMCG MNCs in the UAE. The marketing strategies of the MNCs that belong to the FMCG sector might vary from the other sectors. The study can be conducted on the MNCs of other industries to assess the commonly used international business strategies. The study focused on comparing the marketing strategies of the FMCG MNCs practiced in the UAE with that of the home country. It does not highlight how the strategies of the FMCG MNCs practiced in UAE are different from the other countries. In order to make the study more viable, further research is recommended.

Development of Value Productivity in Czech Chemistry Industry

Jiří Klečka, University of Chemistry and Technology Prague, Department of Economics and Management, Prague, Czech Republic, jiri.klecka@vscht.cz
Dagmar Čámská, Czech Technical University in Prague, The Masaryk Institute of Advanced Studies, Department of Economic Studies, Prague, Czech Republic, dagmar.camska@cvut.cz

Abstract

This paper focuses on the level and development of productivity in chemistry industry in the Czech Republic. The paper discusses the total productivity as well as partial productivities. The used data sample covers the time period 2009-2014 which contains the development during and especially after the last global economic crisis. The development is compared during and after the crisis, respectively the reaction of businesses to the crisis. This contribution identifies and analyzes the value productivity which reflects the level and changes in the technical and economic efficiency of production factors. The value productivity is an important factor in achieving the corporate performance. The value productivity is used in the contemporary concept which works not only with the efficiency of inputs consumption but also with the efficiency of employed capital. The approach used in the paper enables to describe analysed indicators statically as well as dynamic the analysis.

Keywords: value productivity, total and partial productivities, chemistry industry, Czech Republic

Introduction

The value productivity is a key factor in achieving the corporate performance and competitiveness. The position of the Czech Republic in competitiveness rankings is not optimal but the weaknesses are more connected with inputs than outputs (Nečadová and Scholleová, 2011). The topic of productivity is very often discussed by researchers as well as in practice because increasing productivity leads to higher level of corporate performance and it is also a part of national or regional positive development. The productivity of production factors presents a concept which measures the effect of technical changes in the productivity and it represents driving motor of growth (Praag and Versloot, 2008). The concept can be measured on the level of individual enterprises as Hayes (1988) or on the level of one industry branch as Machek and Špička (2014), Novotná, Volek and Fučíková (2014) or Klečka and Čámská (2013). Differences among authors can be connected for example with the focus of productivity indicators. The most traditional indicator covers the area of labour productivity as in Novotná, Volek and Fučíková (2014). Employees can be very important source of competition advantage nowadays. Research of Čámská (2012) proves that employees were a hidden source for managing the last global economic crisis in the Czech Republic. The old fashioned concept of productivity does not take into account capital as one production factor and it abstracts from the costs of capital employed. Nowadays authors work more with the modern approach – value productivity respecting costs of capital employed – as Machek and Špička (2013) or Klečka (2013).

This paper covers the value productivity on the level of one specific industry branch. The paper's aim is to analyse the level and development of value productivity in the chemistry industry. The main motivation is external shock caused by the last global economic crisis. The authors usually differ how they compute the productivity indicators and how they work with price changes and therefore the following chapter introduces the used methods.

Productivity

Productivity can be generally defined as the efficiency of using production factors in manufacturing process, or widely in a production process, whose results are tangible as well as intangible outputs (Klečka, 2011). The productivity can be discussed on the level of the country (macroeconomic level) or on the level of enterprises, detail in Hayes (1988). This paper aggregates enterprises' productivities on the level of the specific industry branch, namely chemistry industry, in the Czech Republic. That could be called as mezzo economic productivity.

Two basic types of productivities can be distinguish (Craig and Harris, 1973) – total productivity (equation 1) and partial productivity (equation 2).

$$\text{total productivity} = \frac{\text{total output}}{\text{total input}} \quad (1)$$

$$\text{partial productivity} = \frac{\text{total output}}{\text{partial input}} \quad (2)$$

Used ratios

The equations 1 and 2 are too general and they cannot be used for fulfilling the paper's aim. This chapter shows how the productivity ratios are modified for the further use. The choice for the indicators used in the analysis has been a compromise between the paper's aim to reflect the value productivity in the contemporary sense and limited data availability which will be specified later. This approach has been used repeatedly by authors (recent works: Klečka and Čámská (2013) and Klečka (2013).

The total productivity ratio

The total productivity takes into account all types of outputs as well as inputs. The contemporary concept of productivity expresses the value of inputs as the costs of consumption (and depreciation plus amortization) and costs of capital employed (components of assets, converted to flow-related capital costs).

$$\text{Total productivity} = \frac{\text{Total revenues}}{\text{Costs of consumption and binding of inputs}} \quad (3)$$

$$\text{Costs of consumption and binding of inputs} = \text{Total costs (accounting)} - \text{interests} + \frac{WACC}{1 - t} \times \text{Total assets} \quad (4)$$

Production and production factors are reflected in the broadest sense – not only for operational part, but also financial and extraordinary activities in enterprises. The total productivity ratio in the contemporary concept is an alternative to the economic profit or the indicator EVA.

This contribution uses the constant price of capital employed (rate of the inputs binding costs) for all reporting period and for all analysed enterprises. This constant rate is equal to WACC for the year 2014 for the chemistry industry in the Czech Republic. The constant value of WACC is 9.56% (Ministry of Industry and Trade, 2015) and the level of taxation is equal to 19%.

The partial productivity ratios of inputs consumption

The partial productivity ratios are focused only on the selected production inputs and the experimental part is based on following ratios.

$$\text{Productivity of consumption (depreciation) of an input} = \frac{\text{Total revenues}}{\text{Costs of consumption of an input}} \quad (5)$$

The costs of consumption are expressed as the difference between total costs and interests of debts.

$$\text{Productivity of consumption of material and energy} = \frac{\text{Operating revenues}}{\text{Costs of material and energy}} \quad (6)$$

The equation 6 uses narrower revenues because using only the main part of revenues increases the explanatory power. Operating revenues are used also in other indicators (7, 8 or 13). In the case of labour productivity we even use only the value added because this numerator is used in the theory and practise for decades. Due to the fact that authors did not have available the information about number of employees in the analysed enterprises personal expenses have been used as the input for computation of labour productivity.

$$\text{Productivity of consumption (depreciation) of fixed tangible and intangible assets} = \\ = \frac{\text{Operating revenues}}{\text{Depreciation of fixed tangible and intangible assets}} \quad (7)$$

$$\text{Productivity of consumption and binding of fixed tangible and intangible assets} = \\ = \frac{\text{Operating revenues}}{\text{Depreciation} + \text{Costs of fixed tangible and intangible assets binding}} \quad (8)$$

The above mentioned costs of binding are expressed as $WACC*(1-t)^{-1}$ multiplied by the value of fixed tangible and intangible assets.

$$\text{Labour productivity} = \frac{\text{Value Added}}{\text{Number of employees}} \quad (9)$$

The partial productivity ratios of inputs binding

The binding productivity ratios follow the contemporary concept of the value productivity. The costs of binding used in the denominator of formulas are expressed together at the end of the sub-chapter.

$$\text{Productivity of inputs binding} = \frac{\text{Total revenues}}{\text{Costs of inputs binding}} \quad (10)$$

$$\text{Productivity of fixed tangible and intangible assets binding} = \\ = \frac{\text{Total revenues}}{\text{Costs of fixed tangible and intangible assets binding}} \quad (11)$$

$$\text{Productivity of current assets binding} = \frac{\text{Total revenues}}{\text{Costs of current assets binding}} \quad (12)$$

$$\text{Productivity of inventories binding} = \frac{\text{Operating revenues}}{\text{Costs of inventories binding}} \quad (13)$$

The cost of binding are expressed as $WACC*(1-t)^{-1}$ multiplied by the value of examined assets (equation 10 – total assets etc.)

Time indices of productivity

The static ratios of value productivity have usually equivalent explanatory power or even just same as some ratios of financial analysis. Financial analysis is even more used in practice. In contrast, the dynamic indicators of value productivity have the potential to capture the size and impact of changes in productivity. There is a need of data about inputs and outputs in prices and physical volumes. The apparatus for the value productivity in the contemporary sense on the micro economical level is in detail described by Klečka (2008).

Such specified data for an analysis of the value productivity in the chemistry industry were not available. At least effect of price changes and the impact of changes in physical volumes were removed partly by using only the ratios of productivity and index comparison. The changes of prices are compensated because of the similar trend of price development of outputs and inputs. On the other hand significant price changes between inputs and outputs would have caused that values of productivity indicators show changes in productivity although the cause of their change is caused only by the price differences. We have to take seriously into account this possible limitation of explanatory power caused by incomplete data specifications. Furthermore, the effect of price changes is reduced by the fixation of costs of capital employed. The development of productivity is expressed as standard time base indices whose content is obvious from further presented figures.

Development of productivity of selected companies operating in the chemistry industry in the Czech Republic

The chemistry industry is an important (third largest) industry branch in the Czech Republic (Ministry of Foreign Affairs, 2011). It proves the level of country development because this kind of industry is intensive to labour force, sufficient amount of raw materials, water and electricity. Products of the chemistry industry are important for other industry branches. The Czech chemistry sector can be divided into several areas. These areas are basic chemicals, refined petroleum products, pharmaceutical products, rubber and plastic products and also paper products. The main share creates basic chemicals (64% of total revenues) and pharmaceutical products (17% of total revenues). Shares of other 5 product areas are significantly lower: production of chemical specialties and fibres (9%), manufacture of cleaning and cosmetic preparations (5%), manufacture of paints (4%), manufacture of pesticides and other agrochemical products (1%).

This paper with its analysis builds on previous works of authors. These works contain the analysis of total productivity in the case of metallurgical industry and automotive industry in the Czech Republic (Klečka and Čámská (2013) and Klečka (2013)). As it has been already mentioned this paper uses analogical methodology.

Data sample

The analysis is based on the data of 500 enterprises belonging to the chemistry industry in the Czech Republic. According to CZ-NACE following sectors are involved – CZ-NACE 20 Manufacture of chemicals and chemical products, CZ-NACE 21 Manufacture of basic pharmaceutical products and pharmaceutical preparations and CZ-NACE 22 Manufacture of rubber and plastic products. Selection criteria were data availability in needed structure and the amount of employees exceeding 10.

The 500 analyzed chemistry enterprises had the aggregate value of assets 279 421 084 000 CZK and aggregate value of revenues was equal to 410 145 448 000 CZK in 2014. It should be noted here that the numbers and proportion of enterprises have been affected by the data availability in the corporate database and therefore the data do not indicate the actual numbers of companies in the chemical industry branches. On the other hand the analysis is not distort because of observed productivity characteristics which are expressed in relative terms and not absolute terms.

Results

This part is dedicated to results which will be displayed in several figures and commented as well. The figures generally show differences between partial productivity and declines and subsequent different fast “recoveries” of several partial productivities in the context of the time period after 2009. This period is connected with crisis recovering. The total productivity of chemistry enterprises was 1.0056 in 2009, after they year 2010 it slightly increased (1.0276 in 2011), around the year 2012 it was followed by a slight decrease (at 1.0044) and for the end of analysed period the slight grow was again observed (1.02446 in the year 2014). The development of value productivity is displayed in figure 1. The value of total productivity can be interpreted as the value of output in CZK for 1 CZK of value of consumption and costs of capital employed.

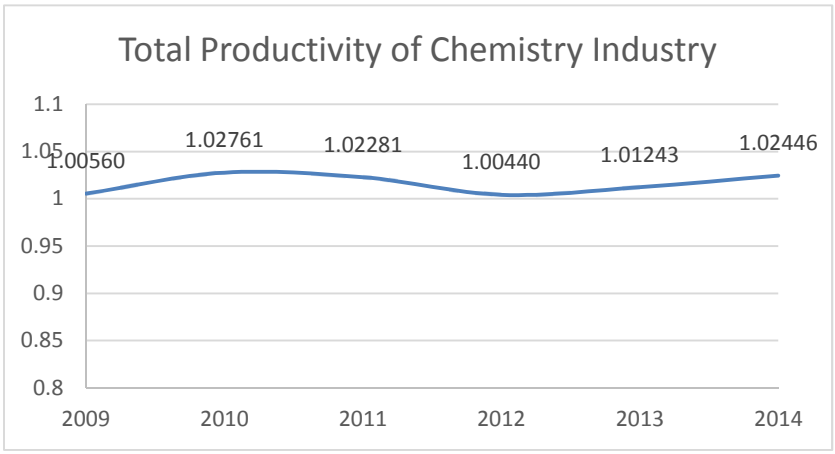

Fig 1. Total productivity (The value of output in CZK / the value of consumption and binding of inputs in CZK), Source: authors

Previously analysed industry branches as metallurgical industry (Klečka and Čámská (2013)) or automotive sector (Klečka (2013) had another development of productivity. Logically these industry sectors are more cyclical than the chemistry industry. In the year 2009 the total productivity was under one (0.958 for automotive industry without car manufactures and 0.857 for metallurgy). After the crisis a systematic slight increase occurred but till 2011 the value of total productivity remained under one. On the other hand in the case of the chemistry industry the total productivity was above one even in the year 2009. It means that this industry was able to retain a positive economic profit.

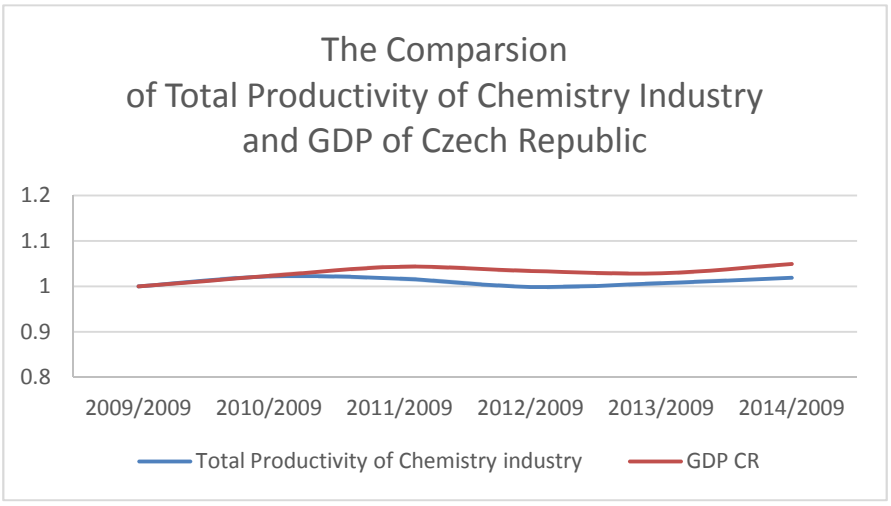

Fig 2. The comparison changes of Total productivity and GDP Czech Republic (base indices, the year 2009 = 100, GDP in constant prices), Source: authors

The figure 2 illustrates the comparison between the development of the value productivity of the chemistry enterprises and gross domestic product of the Czech Republic. It is necessary to take into account that milder growth of chemistry industry's productivity started from the higher level. As it was already discussed this level had not decreased under one which represents the ability to generate economic profit. This is displayed by figure 3.

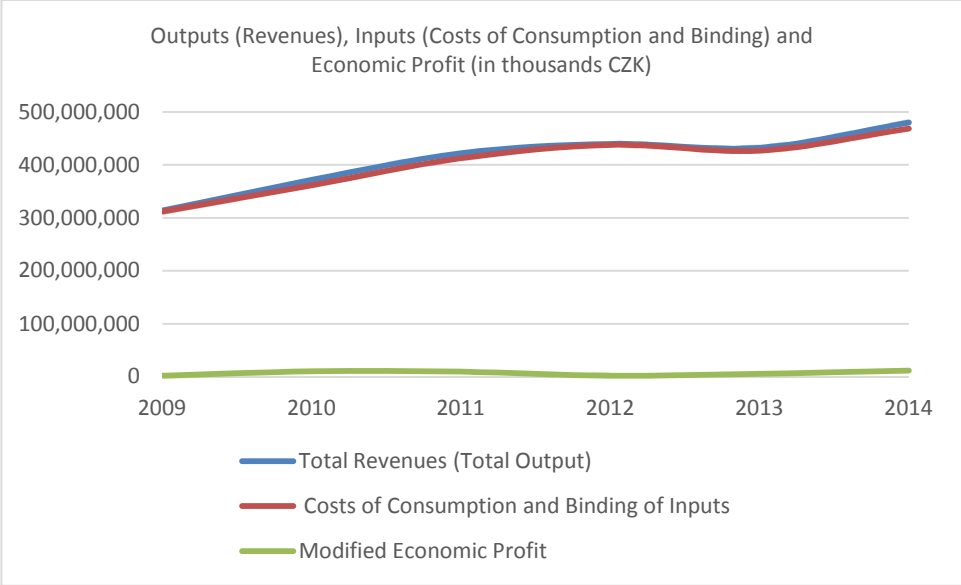

Fig. 3: Revenues, costs of consumption and binding of inputs and modified economic profit (in thousands CZK), Source: authors

Figures 4-6 show significant differences in the development of particular partial productivities. Smaller (bigger) change of value of particular productivity depending on the production volume changes (especially on the decrease) are a consequence of bigger (smaller) enterprise adaptability during usage of particular production factor. It is valid only in the case of assumption that productivity change is not distorted by high price differences of inputs compared with price differences of outputs. This has been already discussed before.

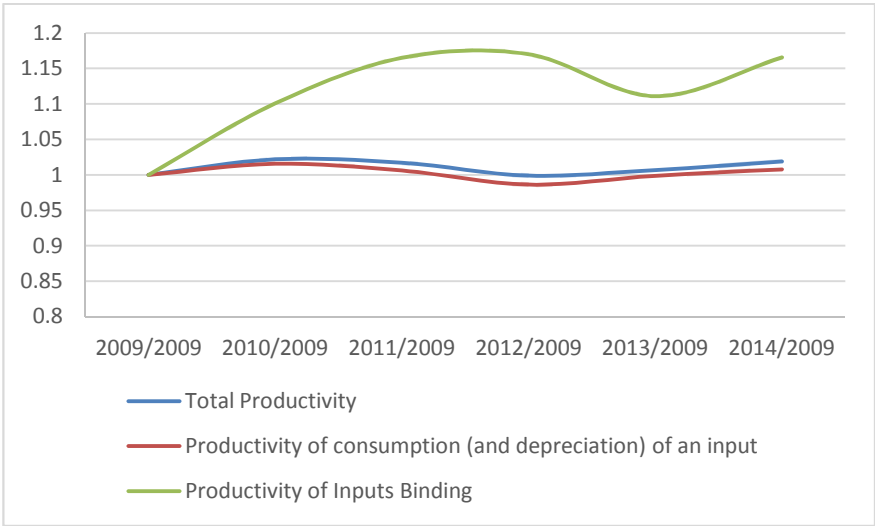

Fig 4. Two main partial productivities (base indices, the year 2009 = 100), Source: authors

Figure 4 displays the development of total productivity and two main partial productivities. It means productivity of consumption inputs and productivity of capital employed (of inputs binding). Figure 5 is focused on the partial productivities from the group of productivities of consumption inputs. Figure 6 is focused on the partial productivities from the group of productivities of capital employed.

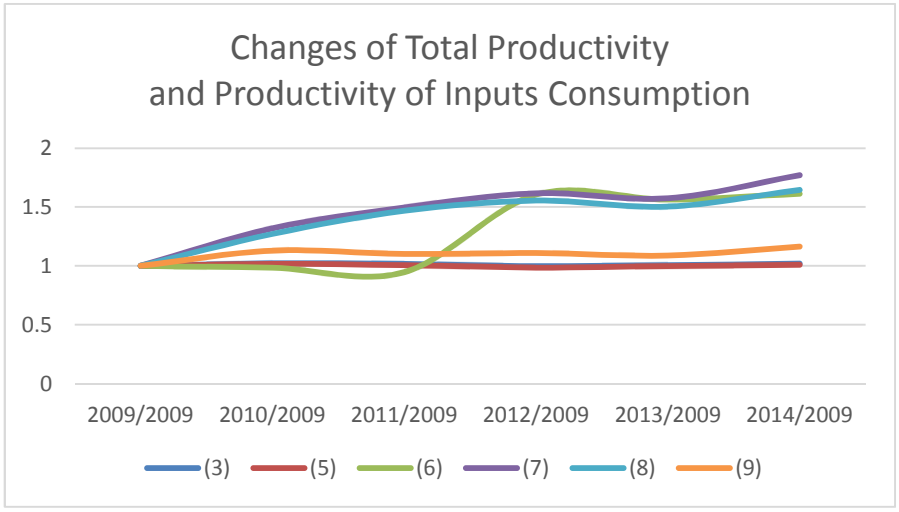

Fig 5. Changes of total productivity and partial consumption productivities (the year 2009 = 100), Source: authors

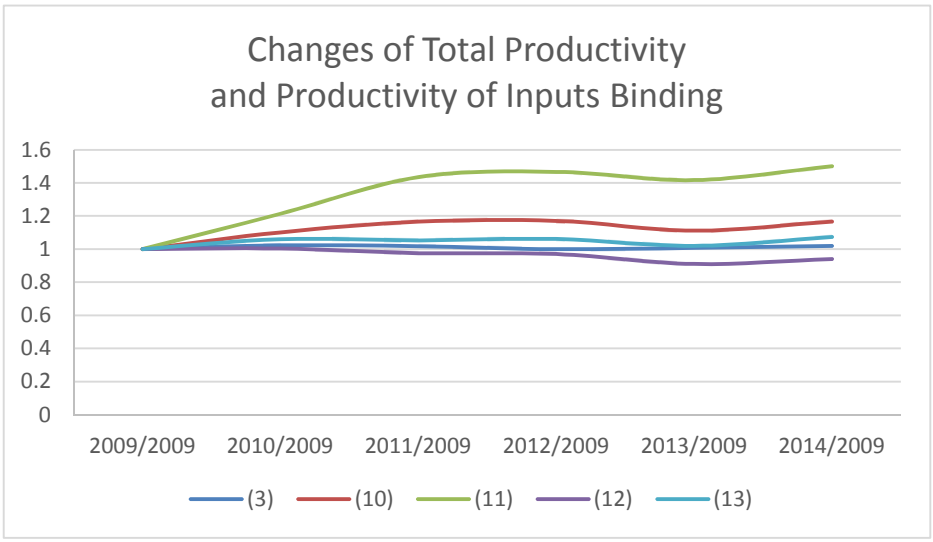

Fig. 6: Changes of total productivity and productivities of capital employed (the year 2009 = 100), Source: authors

Discussion

Shapes of curves enable to distinguish for which production factors the enterprise (th industry) is more or less adaptable. In the case of some production factors it can be more flexible, for others less flexible, more fixed. The curves with big (deep and long) decline are characteristic for lower flexibility.

Measured characteristics are relative. The influence of each production factor does not depend only on the shape of its curve mentioned above but also on the consumed amount which can be expressed by its costs or proportion on costs structure. The share of costs of inputs consumption was 92.75% and the share of costs of capital employed was 7.25% in the whole sample for the whole analysed period. It significantly influences the changes for our analysed data sample. The share of costs significantly influences how the partial productivities have effect on the total productivity.

Conclusion

This paper was focused on the level and development of value productivity. Total value productivity as well as particular partial productivities were covered. The computations analyses were done on enterprises belonging to the chemistry industry. The data sample contained 500 business entities and the analyzed time period covered the years 2009-2014. The changes of productivity in the case of the chemical industry were very slight although the production volume changes were huge. The production volume has increased since 2009 when it reached its bottom because of the global economic crisis. Small changes in productivity as well as retaining the ability to create economic profit (or positive economic value added) prove that the chemistry industry has big adaptability. The motivation for further research work is a comparison of adaptability among industry branches as well as analyzing cyclical character of industry due to economic cycle.

Consumer Attitudes towards Brands in Relation to Price

Dagmar Weberová, Faculty of Multimedia Communications, Tomas Bata University in Zlin, Czech Republic, e-mail: weberova@fmk.utb.cz
Lenka Ližbetinová, Faculty of Corporate Strategy, The Institute of Technology and Business in České Budejovice, Czech Republic, e-mail: lizbetinova@mail.vstecb.cz

Abstract

The objective of this paper is to evaluate buying behavior and consumer preferences of consumers in the Czech Republic according to the attributes of price and brands. The evaluation is based on data obtained from primary research focused on the behavior and preferences of consumers to brands. In addition, these results are compared with the outcomes of the same oriented research conducted in the Slovak Republic. In the Czech Republic, research was carried out through a questionnaire survey and structured interviews during October and November of 2014. This article provides a more detailed view with respect to specific structures of the Czech consumers.

Keywords: attitude – brand –price – respondents – statement

Introduction

Data analyzed and presented in this article look at attitudes of Czech and partially also Slovak consumers towards foreign and domestic brands from the perspective of price. Consumer analysis is based on the following socio-demographic factors: gender, age, net income, educational attainment, and the size of municipality. Findings provide a unique insight into consumer behavior (Stopka et. al, 2015; Mooij, 2011; Schiffman et.al, 2004) and attitudinal information on how consumers perceive foreign and domestic brands in relation to price (Starchon, 2014). Furthermore, companies are often exposed to compromising between low price and high quality, however, in many product classes there is a well-defined breakdown between those customers concerned first about price and others who are willing to pay extra for high quality and features (Aaker & Mcloughlin, 2010, p28-29). So the results this research survey may help marketers understand why consumers behave in a certain way in the fast changing environment and what their preferences are.

Materials and Methods

The main objective of this article is to evaluate buying behavior and consumer preferences in the Czech Republic according to the attributes of price and brands. These findings are compared with data available from a similar research study carried out in the Slovak Republic (Smolkova, 2013). The outcomes presented in the article are based on primary research conducted in the Czech Republic in the period of October and November of 2014 by the Department of Marketing Communications, Faculty of Multimedia Communications, Tomas Bata University in Zlin. The research study was focused on brand perception among Czech consumers and was based on selection of specific criteria (Mason, R et. al, 1998; Krizanova et. al, 2013). The sample of respondents consisted of residents of the Czech Republic older than 18 years. The sample was determined on the basis of quota sampling based on the principle of division of the same proportion of selected properties of the elements according to population (Kotler and Keller, 2006; Aaker et. al, 2007). Quotas based on age, gender, income, size of municipality and districts in the Czech Republics were determined for the purpose of this research. Quota distribution of these socio-demographic data is based on parameters obtained from the Czech Statistical Office (2014).

The sample included 1028 respondents and all the chi-square tests were calculated with a confidence level of 0.05 and the accepted tolerance of 3% accuracy. Respondents were approached via an electronic questionnaire and personal interviews. Within this research, respondents were asked a total of 38 questions, of which the first three were open and investigated the spontaneous brand awareness and associations with the Czech brands. Then a series of 28 Likert scales followed – these were

designed to detect consumer preferences and their attitudes towards domestic and foreign brands. Scales had a form of statements and respondents had the opportunity to express themselves in the range of five points: I fully agree – I partly agree – I do not know – I partly disagree – I fully disagree. The last part of the questionnaire consisted of seven questions and dealt with basic socio-demographic characteristics of respondents. In this article, partial outcomes of this research are presented; they deal with the attitudes of respondents towards the importance and effect of prices on brand perception. Data were processed with the help of the SPSS (IBM Corporation, 2015).

Furthermore, in this article, research results are compared to the results of primary research carried out by Smolkova et al (2013) at the Faculty of management, Comenius University in Bratislava in 2013. Data were gathered in the period of January to April 2013 by means of personal interviews and an online questionnaire available on the Internet. The group of respondents was based on the same method of quota selection and consisted of Slovak citizens aged 16+. Altogether, 1067 respondents were questioned – this is a comparable sample with the research study conducted in the Czech Republic.

Table 1 Structure of the Czech and Slovak respondents according to the selected criteria

Criteria	**Czech Republic**	**Slovakia**
Gender	Number	Number
Male	505	504
Female	523	518
Age		
18-29 years old	208	278
30 - 39 years old	273	228
40 - 49 years old	185	189
50- 59 years old	160	245
60+	130	87
Education		
Primary education	113	75
Secondary school without graduation exam (A-levels)	284	61
Secondary school with graduation exam (A-levels)	423	497
University graduates	208	371
Size of municipality		
to 2 thousand inhabitants	160	169
2 - 5 thousand inhabitants	103	138
5 - 10 thousand inhabitants	71	73
10 - 20 thousand inhabitants	95	119
20 - 50 thousand inhabitants	169	152
50 -100 thousand inhabitants	142	191
over 100 thousand inhabitants	286	187

Czech Republic		**Slovakia**	
Net household income	**Number**	**Net household income**	**Number**
less than CZK 9,000	18	less than EUR330	70
CZK 9,001 – 15,000	90	EUR 331 - 500	118
CZK 15,001 – 21,000	120	EUR 501 - 660	125
CZK 21,001 – 27,000	153	EUR 661 - 900	174
CZK 27,001 – 33,000	146	EUR 901 – 1,330	206
CZK 33,001 – 39,000	132	EUR 1,331 – 1,660	128
CZK 39,001 – 45,000	99	EUR 1,661 – 1,990	52
CZK 45,001 – 51,000	86	EUR 1,991 – 2,320	43
CZK 51,001 – 57,000	43	EUR 2,321 – 2,660	16
CZK 57,001 – 63,000	40	more than EUR 2,661	54
CZK 63,001 – 69,000	25		
over CZK 69,001	74		

Note: Slovakia adopted the common European currency (EUR) in 2009. The Czech Republic has not adopted it yet. 1 Euro is approximately 27 CZK – Czech koruna, i. e. "crown".

The questionnaire in Slovakia had a similar form as in the Czech Republic but there was a different number of scale questions focused on consumer preferences – 27 questions and only five questions concerning basic socio-demographic characteristics of respondents were asked. Data from research conducted in the Slovak Republic were processed in the Statgraphic Program (Statpoint Technologies, 2015) and in the R statistical software (The R Core Team, 2015). Table 1 shows basic data about the structure of respondents in both the Czech and Slovak respondents. In the Czech Republic, additional facts were investigated such as the number of employed household members and regional belonging.

Results and discussion

The results of the research focused on the importance of price based on respondents' attitudes towards brands and branded products are presented through their reactions to the following statements:

- „I prefer to buy cheap products."
- „I am willing to pay more for my favorite brand."
- „I am willing to pay more for the Czech/Slovak brand."
- „Foreign brands are cheaper."
- „Foreign brands are easier available than the Czech/Slovak ones."

In order to provide a clear overview the results of respondents' attitudes are grouped according to the selected criteria of the respondents' structure (gender, age, education, net income, and size of municipality). Figure 1 shows results in the form of a weighted arithmetic mean of respondents' answers in the scale: *I fully disagree* (-2), *I partly disagree* (-1), *I do not know* (0), *I partly agree* (1), and *I fully agree* (2). The attitudes of men and women to the statements are similar and there is only one maximum deviation of 0.2 referring to the statement that "foreign brands are easier available than the Czech ones" – in this case both men and women partly agree with the statement (23.25% of men and 28.8% of women partly or fully agree with it). The option of partial agreement is the most frequent answer of both men and women. Respondents' attitudes towards popular brands are very positive, both men and women are willing to pay more for their favorite brand.

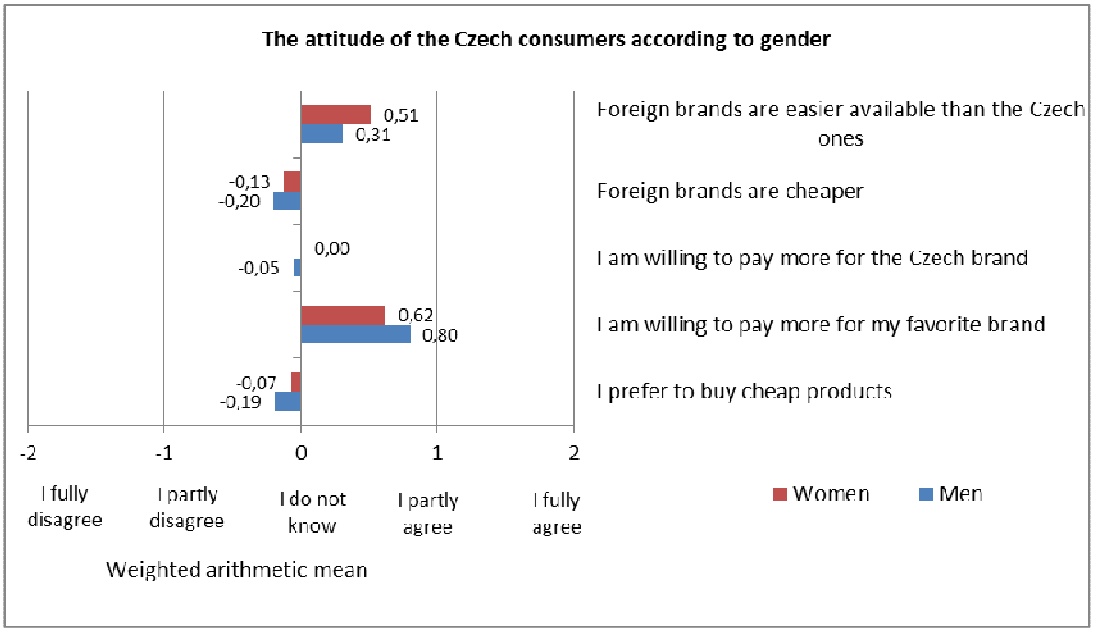

Fig 1. The attitude of the Czech consumers towards brands in relation to price based on gender
Source: Own (based on research)

According to the research results, a popular brand is far more important for men than for women (the difference makes 7.66%). The attitude of respondents to pay more for the Czech brand is rather indecisive – this indicates that experience and satisfaction with a particular brand regardless of its origin is more important for respondents than the fact that it is a domestic (Czech) brand. The question of buying cheap brands is not really important for respondents, what is taken into account is, as it has already been mentioned, experience and satisfaction and these are appreciated by more men than women who seem to be more price conscious when making their buying decision. Respondents disagree with the statement that foreign brands would be cheaper, so their price is no reason why consumers should buy them. The problem is that Czech brands are often less available to them than foreign brands.

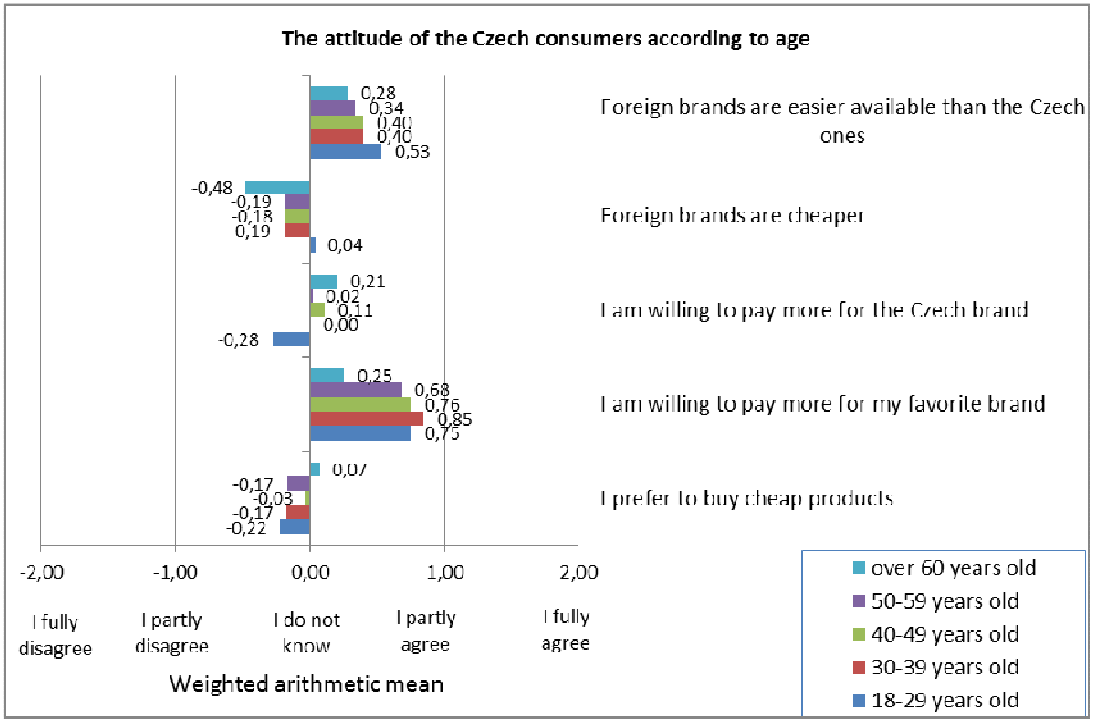

Fig 2. The attitude of the Czech consumers towards brands in relation to price based on age
Source: Own (based on research)

Based on the respondents' age structure (Figure 2), their attitude towards brands in relation to price reveals some significant differences in orientation. A different approach is seen by consumers over 60 years old who tend to prefer cheaper products (50% of them buy cheaper products and 33% disagree with the statement). In addition, they are more loyal to the Czech brands (51.5%) than other age categories. And unlike other age categories, respondents in this category are less willing to pay more for their favorite brand (51.5% of them is ready to pay more for their favorite brand – this is less by 19.7% than in other categories. From their point of view, foreign brands are not cheaper (48.5%), however, these brands are often easier available than domestic ones (claimed by 46.9%, and 39% remained indecisive). The smallest inclination to Czech brands is shown by the youngest age category (18 to 29 years old) – respondents in this category are not willing to pay more for domestic brands (this was claimed by 45.7% while 23.5% were indecisive). Respondents in this category appreciate easier availability of foreign brands in comparison to domestic ones (53.6%); however, they are indecisive in their attitude to a lower price of foreign brands. What is important for this category is the question of the popularity of the brand itself (71.1%) and the fact whether this brand is cheaper or more expensive does not play an important role.

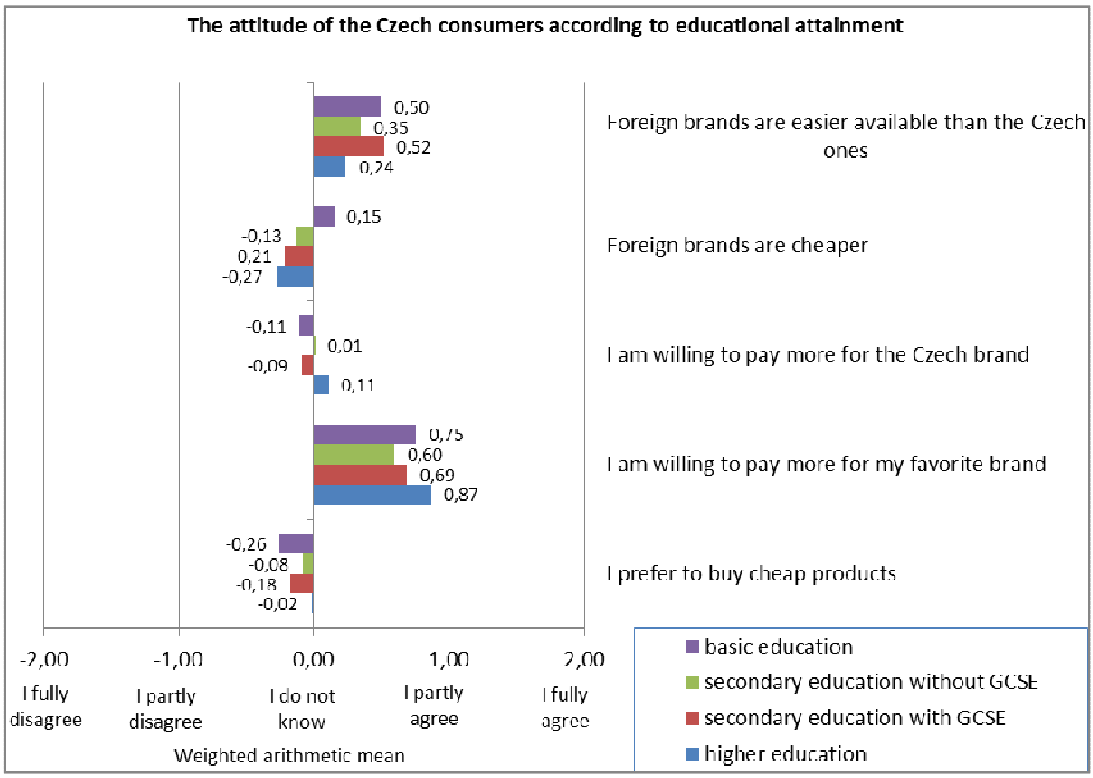

Fig 3. The attitude of the Czech consumers towards brands in relation to price based on education

Source: Own (based on research)

The results compared according to the level of educational attainment of respondents (see Figure 3) reveal the difference in attitudes between the consumers with basic and higher education. Respondents with basic education tend to disagree with orientation to cheap products (55.8% respondents disagree and 42.5% of them agree with the statement), they hold a neutral to negative attitude toward the willingness to pay more for Czech brands. Instead, they are willing to invest more in their favorite brands (71.7%) and as the only group they tend to claim that foreign brands are cheaper (38.05% respondents agree and 34.5% are indecisive). They also agree with the statement that foreign brands are easier available than the Czech ones (55.75% of respondents agree, 26.55% do not know and 17.7% disagree). Respondents with higher level of education take a more neutral attitude to cheaper products and they are most willing to pay more for their favorite brand (76.92%) and, compared to other groups, also for Czech brands (47.12%). At the same time, they rather disagree with the fact that foreign brands are cheaper (42.3% disagree and 30.8% of respondents do not know) but they consider them for easier available (40.87%). Groups of respondents with secondary education tend to focus on cheap products; the popularity of the brand plays an important role in their choice (69% of respondents with GCSE (General Certificate of Secondary Education) and 61.27% of respondents with completed secondary vocational school). The fact whether it is a Czech brand plays no significant role to them. Like consumers with higher level of education they do not think that foreign brands are cheaper but they consider them for easier available (54.74%).

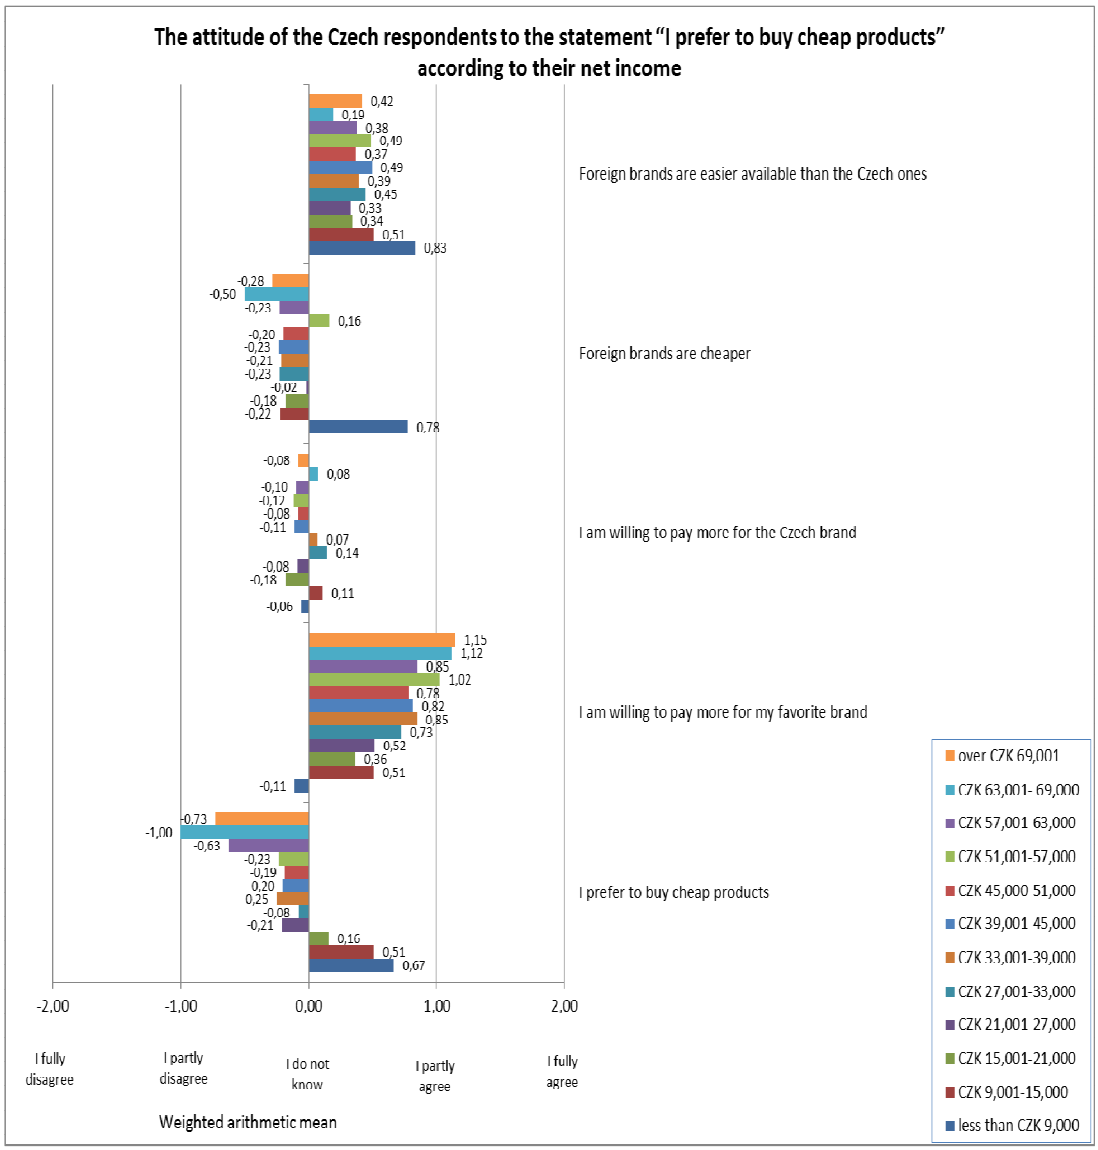

Fig 4. The attitude of the Czech consumers towards brands in relation to price based on net household income

Source: Own (based on research)

In this research survey, respondents are divided into 12 categories taking into consideration their net household income (see Figure 4). Results show that respondents with income up to CZK 15,000 prefer to buy cheaper products (62.04%), while fewer respondents with net household income up to CZK 21,000 tend to do the same (the difference is 7.9%). The attitude toward buying cheap products tends to be more negative at other groups of respondents whose income exceeds CZK 21,000 and the question of price plays in buying decisions a far less significant role at the group with a net income over CZK 57,000. The category of respondents with the lowest net household income (up to CZK 9,000) shows compared to other income categories, significantly different behavior. The most decisive factor for this group is the price of the product and it is irrelevant whether it is their favorite or domestic brand. They also state that foreign products are cheaper (55.55%) and very easy to obtain (83.33%). Other categories also tend to agree with the statement that foreign brands are easier available for consumers but they tend to disagree that these brands would be cheaper (this is stated by 40.8% of respondents and 31% of them do not know). They do not focus on cheap products and they are willing to pay more for their favorite brands (69.1%) but their willingness to pay more for Czech

brands is rather ambiguous (41.39% of respondents are willing to pay more and 40.89% of them is not willing to do so while 17.72% of them do not know).

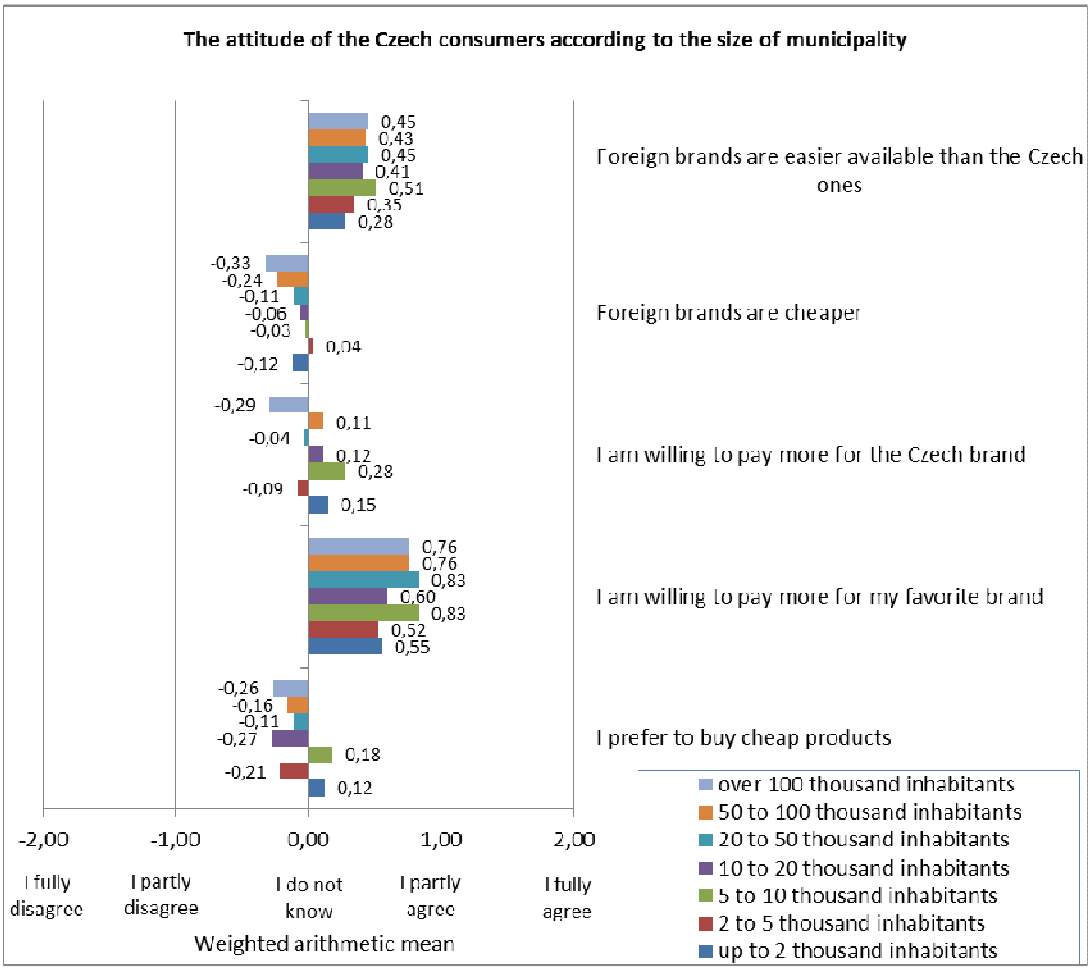

Fig 5. The attitude of the Czech consumers towards brands in relation to price based on the size of municipality

Source: Own (based on research)

Looking at the attitudes according to the size of respondents' municipality (see Figure 5), it can be stated that the bigger the size of municipality the more space is available for purchasing of more expensive products (40.37% of respondents living in a municipality up to two thousand inhabitants disagree with the statement and this tendency is gradually rising up to 52.8%). This fact is also apparent when looking at cheap foreign brands where respondents living in bigger municipalities tend to the statement that foreign brands are not cheaper (44.06% respondents living in municipalities with over 100 thousand inhabitants) and at the same time the inclination to prefer Czech brands in case these are more expensive is on the decrease (this is preferred by 32.17% and not preferred by 48.95% of respondents living in municipalities with over 100 thousand inhabitants). With the increase of population in the municipalities respondents indicate an easier availability of foreign brands over domestic ones. It is apparent that all categories prefer favorite brands even at the cost of additional payment and this preference is increasing with the size of the municipality.

Comparison with Slovakia

Five questions (see Figure 6) were used to investigate respondents' attitudes in relation to the importance and influence of price on brand perception. Comparison of the weighted arithmetic mean values of responses in the rating scale makes it possible to get a brief overview of the results achieved in the Czech Republic and Slovakia (Smolkova et al, 2013; Smolkova. 2013). So how important is

price in relation to brands? In both countries, consumers are primarily focused on their favorite brands (0.81/Slovakia and 0.71/Czech Republic), they are willing to pay more for these brands (in Slovakia focus on favorite brands is higher by 0.1 than in the Czech Republic).

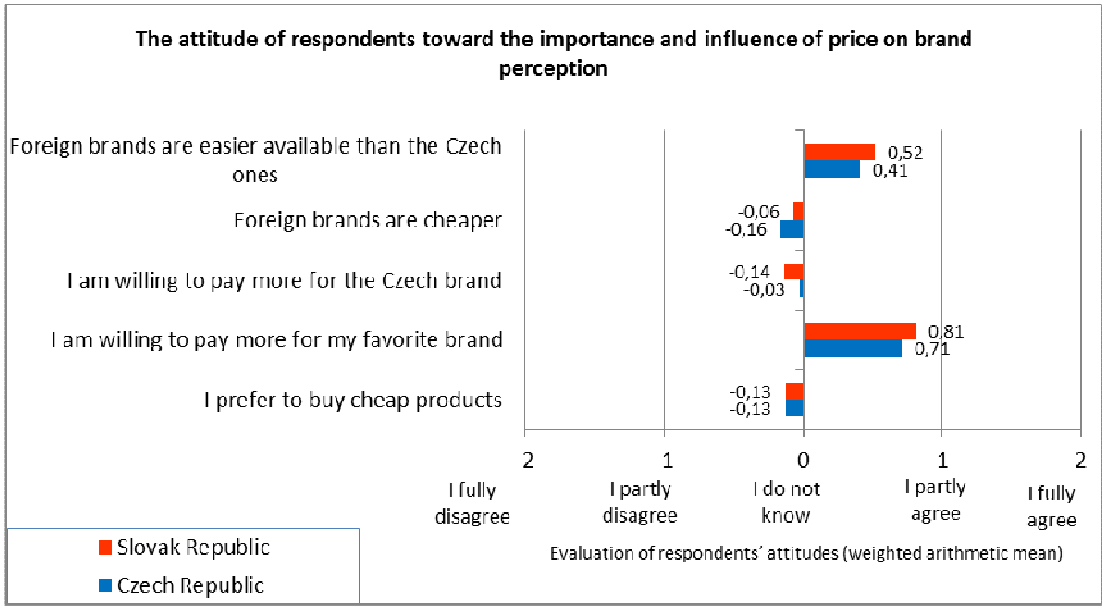

Fig 6. The attitude of respondents toward the importance and influence of price on brand perception

Source: Own (based on research)

The fact that respondents are willing to pay more for their favorite brand is not entirely clear at domestic brands (the willingness of Slovak respondents to pay more for the domestic brand is lower by 0.11 than the willingness of Czech respondents). Price does not play such a substantial role in the majority of respondents, compared to the question of popularity of the product brand. This focus on brand is more evident at Slovak respondents, and this fact enables companies to introduce more expensive products on the Slovak market.

Conclusion

Results obtained from the research survey provide a valuable insight in consumer behavior in the Czech Republic. By analyzing consumer attitudes according to their gender, it can be seen that in comparison to female customers, male consumers tend to be less price conscious because they are willing to pay more for their favorite brands. Therefore emotional aspects are in consumer behavior of great importance (Tislerova, 2015; Potkany et. al, 2015). If brands are able to offer emotional benefits to consumers, a vast majority of them is willing to pay more for the brands they like and love. Moreover, these consumers tend to be very loyal, thus the ability to create emotional benefits associated with a particular brand should be part of a company's marketing strategy (Lorincova et. al, 2014). Concerning the age of respondents, consumers older than 60 years have not only the strongest tendency to buy cheap products but also the highest level of loyalty. Considering the level of educational attainment, diverse attitudes toward brand perception and price can be observed. Data obtained from investigating respondents' attitudes according to their net household income bring less surprising results. Price is, of course, a key factor for people with a low net income while it plays no significant role for people with a high income. As can be seen above, consumers are, in general, less willing to pay more for domestic brands. Good quality of branded products (Aaker et al, 2010), systematic emphasis (Solarová, 2015; Rebetak et. al, 2013; Kampf et. al, 2012) on the country-of-origin and competitive pricing policy (Gazquez-Abad et. al, 2016) can contribute to raising consumer awareness so that customers when making their buying decisions pay more attention to the origin of branded products.

Resume

Face à la crise actuelle et aux mutations de la demande touristique, les territoires et les destinations sont tenues de remettre en cause leurs stratégies touristiques. Ainsi, et pour améliorer leur attractivité, les territoires touristiques doivent faire un effort en terme de visibilité et de lisibilité sur le marché national et international.
L'exacerbation de la concurrence entre les destinations conduit de plus en plus de destinations à rechercher un positionnement qualitatif en valorisant les actifs du territoire. Cette logique de différenciation qualitative des territoires a conduit ces dernières années, au développent du marketing territorial et en particulier à l'apparition de multiples labels et marques territoriaux.
Ce papier vise à analyser la pertinence de la mise en place d'une stratégie de marque pour un territoire donné et essayer de montrer comment la marque territoriale, peut être un support pertinent pour asseoir l'attractivité et la différenciation d'une destination touristique en général et la destination «MAROC» en particulier.
Mots clés : attractivité territoriale, destination touristique, marque territoriale, qualité

Abstract

Faced with the current crisis and to the changes in tourism demand, territories and destinations are bound to question their tourism strategies. Thus, and to improve their attractiveness, tourist territories must make an effort to end visibility and legibility on the national and international market.
The increased competition between destinations led more and more destinations to seek a premium positioning by valuing the assets of the territory. This logic of qualitative differentiation of territories has led in recent years to develop territorial marketing and in particular the appearance of multiple labels and territorial brands.
This paper aims to analyze the relevance of the establishment of a brand strategy for a given territory and try to show how territorial mark, may be a relevant support for sit attractiveness and differentiation of a tourist destination General and destination "Morocco" in particular.

Keywords: territorial attraction, tourist destination, territorial brand, quality

Introduction

Face à un environnement instable, un contexte d'hyper-concurrence entre les territoires et des clientèles touristiques à la recherche du sens, d'excellence et du bien être, seuls les territoires porteurs d'une identité forte et des valeurs uniques pourront être compétitifs et attractifs. La marque territoriale peut représenter un cadre d'analyse prometteur dans une logique de développement des positions concurrentielles des entreprises du tourisme et de l'attractivité des territoires.

La marque territoriale est un phénomène en croissance qui offre la possibilité à chaque destination de montrer sa présence, ses attributs, mais aussi d'accroitre sa notoriété, son attractivité et de se différencier

des concurrents. Notre recherche sur la marque de territoire - destination se place d'emblée dans cette perspective.

Notre objectif à travers ce papier est d'analyser la pertinence de la mise en place d'une stratégie de marque pour un territoire touristique et d'essayer de montrer comment la marque territoriale, peut être un support pertinent pour asseoir l'attractivité et la différenciation d'une destination touristique en général et la destination « MAROC » en particulier.

Le tourisme au Maroc est un secteur important dans l'économie nationale, il se base sur les potentialités et les richesses des différentes villes et régions du territoire - pays. L'attractivité de la destination Maroc est fondée sur des données géographiques et culturelles mais également sur les milieux naturels… Ce qui rend leur préservation comme un véritable enjeu pour la compétitivité et la durabilité du territoire. Cependant l'image de la destination Maroc est devenue, ces dernières décennies, floue et moins attractive pour les touristes. C'est une destination qui souffre d'un problème de positionnement claire sur le marché touristique national et international.

Dans ce contexte, pour se repositionner et répondre aux attentes des touristes, le Maroc doit s'appuyer sur ses atouts traditionnels : sa forte identité culturelle, la richesse de son patrimoine naturel et sur la qualité de ses produits. Mais une telle évolution, déjà entamée, exige non seulement le renforcement de la qualité des prestations touristiques mais encore la mise en place d'un système de communication au profit du client potentiel (touriste). Dans ce cadre et selon les recommandations de la cour des comptes à l'office national marocain du tourisme (ONMT), un système de marquage cohérent et crédible peut s'avérer une source d'attractivité pour la destination « Maroc ».

Toutefois, cette réflexion autour de la marque de la destination Maroc ne peut être dissociée de la réflexion globale sur la construction et le développement de la marque Maroc. Cette marque, selon l'institut royal des études stratégiques « IRES », même si elle bénéficie déjà d'un univers culturel attractif à l'étranger, jusqu'à présent elle n'est pas pensée ni promue en tant que telle.

Le présent article développe les leviers de la construction de la marque territoriale en creusant cette liaison entre marque territoriale et destination touristique. Pour traiter cette question, nous allons consacrer la première partie de ce travail au concept d'attractivité touristique , la deuxième partie vise à présenter quelques repères sur les fondements théoriques de toute politique de marquage territoriale et enfin dans la troisième partie nous allons essayer d'appliquer ces raisonnements au territoire touristique «Maroc ».

I. Attractivite Des Territoires Touristiques

Depuis plusieurs années, une grande importance est accordée à la notion d'attractivité, désormais omniprésente dans les discours des politiques, les travaux des consultants et les publications des académiques. Cependant, et selon Hubert Gérardin et Jacques Poirot (2010), il s'agit d'un terme d'utilisation relativement récente, à la signification assez floue et donnant de ce fait lieu à une grande diversité d'interprétations.

L'attractivité est un élément important dans le développement d'un territoire du fait qu'elle contribue à le mettre au devant sur la scène concurrentielle des territoires et elle le rend comme un produit qui doit se vendre pour se développer, elle se voit, en effet, comme impérative pour tous les territoires. Ceci est facilité notamment par l'adoption d'une stratégie de marketing territorial qui permet de mettre en valeur les atouts du territoire et qui favorise le développement, par l'apport des actions marketing qui peuvent être mises en place et qui se traduisent, dans notre cas, par la marque territoriale.

Le marketing territorial détenait et détient encore une place importante notamment concernant l'attractivité et la compétitivité territoriale. Ce marketing pourrait alors être désigné comme étant « l'effort de valorisation des territoires à des marchés concurrentiels pour influencer, en leur faveur, le comportement de leurs publics par une offre dont la valeur perçue est durablement supérieure à celle des concurrents ». (Gollain, 2008).

L'enjeu de l'attractivité consiste à articuler les actions d'acteurs hétérogènes, à favoriser leurs complémentarités et à dégager des synergies sans perdre de vue l'objectif d'un projet de développement pérenne. C'est dans cet ordre d'idée, que les chercheurs dans ce domaine ont envisagé d'étudier l'attractivité d'une destination touristique.

Une destination touristique attractive attire des touristes mais aussi attire et retient les acteurs du tourisme sur son territoire. Une telle destination sera ainsi en mesure de capitaliser sur un portefeuille de ressources naturelles et/ou créées, de se reposer sur une « industrie » touristique structurée, concurrentielle et innovante et de bénéficier de supports institutionnels.
De ceci, nous pouvons avancer que la destination est considérée comme un « territoire-support d'activités » et un « territoire-support de population » pour reprendre les termes de Davezies (2008).
Ainsi, plusieurs conditions sont nécessaires pour développer l'attractivité d'une destination touristique :

- La stratégie adoptée par une destination doit être en mesure de contribuer à la création de valeur ajoutée.
- L'attractivité touristique dépend nécessairement d'un portefeuille de ressources naturelles et/ou créées assimilable à un avantage comparatif.
- Une destination attractive est celle dont l'offre correspond à une demande touristique forte et ciblée ayant une dimension nationale et internationale.
- Enfin, le succès de toute stratégie adoptée par une destination touristique est conditionné par l'existence des supports, tant sur le plan institutionnel que sur le plan gouvernemental, capable de renforcer l'image touristique de la destination, d'encadrer juridiquement la profession, de fixer les normes qualitatives…etc.

De ce qui précède, il convient de signaler que le statut de destination attractive découle de la combinaison de plusieurs éléments d'identification à la fois du côté de l'offre que celui de la demande (Crouch et Ritchie, 1999, 2000; Dwyer et Kim, 2003, Enright et Newton, 2004).

II. Role De La Marque Dans L'attractivite Des Territoires

Sous l'effet de la mondialisation et des crises économiques, de nombreux territoires se sont appropriés la démarche du marketing territorial, ceci est vrai pour le Maroc. Suite à la politique de régionalisation avancée, donnant naissance à une nouvelle répartition et aménagement territorial et à des prérogatives nouvelles aux territoires, et face au phénomène de métropolisation, le Maroc s'est approprié la démarche du marketing territorial en général et la marque territoriale en particulier.

Ce phénomène de constitution de la marque territoriale confirme l'aspiration déjà ancienne des organisations publiques à davantage de légitimité (Laufer, 1980), il illustre la volonté de donner (ou redonner) une lisibilité au territoire et au-delà vise à renforcer l'avantage compétitif de la ville, de la Région ou du pays.
Pour d'autres chercheures et professionnels, le concept de marque pour un territoire est « indissociable de celui de la qualité ». Cette qualité territoriale légitime l'identité du territoire vers l'extérieur et renforce le sentiment d'appartenance pour la population locale. Mais le concept est avant tout un outil marketing et de communication, censé contribuer à la visibilité et à la lisibilité du territoire et donc à sa mise en marché à travers ses caractéristiques fondamentales et représentatives. La marque du territoire est donc, à la fois une fonction défensive de différenciation d'un produit de celui de la concurrence mais aussi une fonction symbolique, identitaire, d'incarnation d'une promesse (Kapferer, 2011)

La construction d'une telle marque doit se baser sur une vision stratégique et un projet de développement pour le territoire (Anholt, 2007 ; Moilanen et Rainisto, 2009). Pour ces auteurs, elle est nécessairement « co-construite » car véhiculée autant par les institutions que par la société civile et le monde économique qui, bien que s'affranchissant de plus en plus des frontières géographiques, font par ailleurs valoir de plus en plus leur ancrage territorial. De ceci, il apparait que la construction d'une marque territoriale se base sur deux piliers fondamentaux, il s'agit de ***l'identité territoriale*** et de ***la mobilisation des acteurs « marque partagée »***.

- ***l'identité territoriale***

La marque territoriale est censée contribuer à la création d'une valeur supplémentaire en débanalisant l'offre, et ce à travers l'identité de territoire. Dans ce sens et selon Rebillard, (2012) « Pour éviter que le territoire ne devienne une entité schizophrène et que les habitants ne rejettent la destination (et les touristes qui la fréquentent) et inversement, pour que les touristes reconnaissent dans le territoire la destination qu'ils ont rêvée, marque de destination et identité territoriale doivent être corrélées»

Dans ce sens, Cerveaux C. (2012) nous rappelle que la première étape dans le processus de création de marque territoriale réside dans l'élaboration du profil identitaire (socle commun imaginaire et des valeurs du territoire) et la délimitation des atouts à mettre en avant.
Il s'agit alors de valoriser ses qualités à des fins de notoriété et d'image, dans ce cadre l'analyse identitaire va permettre d'isoler les qualités intrinsèques du territoire, souvent en lien avec le patrimoine naturel, culturel ou historique. « Un élément de patrimoine possède généralement un sens, pour son détenteur comme pour la communauté . Il est porteur de traditions, d'affectivité, il a été transmis et mérite d'être transmis à nouveau » (de Varine, 2004). L'enjeu donc, même si une marque doit faire rêver, est d'aboutir à une image réelle du territoire.

- ***la mobilisation des acteurs***

Pour réussir, le développement des territoires passe par la mobilisation et la mise en réseau de l'ensemble des acteurs dans une logique pluraliste. Il en est de même pour le projet de marque territoriale, fondé sur une réflexion prospective, collective et partagée par tous (Marie-Eve Férérol 2012). Ce projet est tenu de mobiliser les acteurs et les parties prenantes dans un territoire, on parle alors d'une marque fédératrice. Dans ce cadre, les acteurs du territoire se réapproprient une histoire et une culture, des valeurs communes… Ils se fédèrent autour d'un « socle de valeurs partagées » et sont plus motivés à représenter et à contribuer au succès de la marque territoriale.

Cette idée est vraie aussi pour les destinations touristiques, puisque Rebillard, (2012) considère que « pour qu'une marque de territoire-destination soit à la fois pertinente, pérenne et efficace, pour qu'elle parvienne à structurer le territoire et à fédérer les acteurs économiques, institutionnels, politiques et de la société civile, elle doit être partagée et appuyée par tous ».

III. Marque Territoriale Au Service De L'attractivite De La Destination Touristique « Maroc »

Dans un contexte mondial concurrentiel et instable et pour pouvoir se démarquer**,** la destination « Maroc » est appelée à développer sa « marque pays», et ce afin de mobiliser efficacement et en permanence les potentialités dont elle dispose et de défendre, in fine, ses intérêts stratégiques prioritaires au niveau national et international.

Pour l'heure, et selon une étude stratégique réalisée par l'office national marocain du tourisme « ONMT », le territoire touristique « Maroc » est identifié par les touristes potentiels comme une destination de «la diversité», «des monuments» et «de l'histoire». Cette étude montre également que cette destination souffre selon ces touristes de manque de sécurité, de difficulté de déplacement et d'un manque de confiance dans l'autorité locale.
De même, le tourisme au Maroc est largement concentré sur deux destinations touristiques : Marrakech et Agadir, qui totalisent plus de la moitié des nuitées internationales. Cette concentration géographique ne permet pas de mettre en avant toutes les potentialités du territoire touristique marocain.
Pour pallier cette situation, le Maroc doit développer une visibilité internationale et doit accéder au statut de destination à part entière. Tout en offrant la possibilité à chaque sous destination pour offrir une expérience unique en complémentarité et en cohérence avec les autres sous destinations et avec la destination MAROC.

Comme toute décision marketing, le processus de construction d'une marque territoriale est identifié à celui d'une démarche marketing, avec une phase analytique, une phase stratégique et une phase

opérationnelle (C.-E. Houllier-Guibert, 2012). Cette démarche doit être soutenue par l'articulation entre la dimension intérieure et extérieure de l'image du pays et par l'importance de la veille stratégique pour anticiper les mutations du contexte international, régional et national, mais aussi pour identifier exactement les éléments identitaires distinctifs sur lesquels le pays serait en mesure de construire sa marque.

Dans ce sens, la destination Maroc est tenue de mettre en place une stratégie globale et intégrée de marque « Maroc», de mobiliser les synergies des différents acteurs du tourisme pour la mener à bien et de faire converger ces acteurs dans une même vision pour la promotion de l'image du Maroc. Cette stratégie doit être accompagnée par une communication stratégique ciblée et cohérente, une action indispensable, compte tenu de la multiplicité des intervenants et de la diversité des audiences ciblées.

Ces différents leviers constituent la base indispensable pour créer, mettre en place et développer une marque territoriale aussi stratégique que celle de la marque Maroc en général et la marque territoire - destination « Maroc » en particulier. Toutefois, et dans le souci d'une bonne gouvernance de cette marque, il est recommandé de créer une organisation transversale, il s'agit donc de mettre en place un comité de pilotage qui sera chargé d'élaborer une stratégie marketing sur le long terme, de veiller à sa mise en œuvre et à la mise en place un système d'évaluation pertinent.

De ce qui précède, nous pouvons avancer que le succès de la marque de territoire-destination « MAROC » dépend des conditions majeures suivante, elle doit mettre en valeur l'identité et les valeurs du territoire « Maroc », mettre en place des projets de qualité, être collective, transversale, et porteuse d'une éthique.

Conclusion

Travailler sur la marque territoire – touristique « MAROC » est une nécessité pour pouvoir se démarquer de la concurrence mis aussi pour fédérer tous les acteurs du secteur touristique autour des objectifs communs. Cependant, la construction et la gestion de cette marque est une tâche complexe qui nécessite, pour le territoire en question, d'entamer une réflexion sur ses marqueurs identitaires, ses atouts, son image et ses valeurs à transmettre.

Dans ce sens, plusieurs chercheurs et acteurs du secteur ont exprimé leurs inquiétudes, si la mise en marché d'un territoire aux couleurs d'une marque le réduise à un produit, qu'elle accentue encore le positionnement individualiste du citoyen en consommateur » (Van Santen, 2011).

La création de la marque pour une destination touristique s'avère d'une grande utilité pour améliorer l'attractivité du territoire, cependant le développement de cette marque doit être manié avec précaution, en évitant la multiplication exponentielle des marques (éviter la banalisation), mais aussi en faisant preuve de beaucoup de pédagogie pour faire accepter une marque territoriale à la population et aux acteurs économiques.

Dans ce sens, la destination Maroc est tenue de mettre en place une stratégie globale et intégrée de «marque-Maroc» et de mobiliser les synergies des différents acteurs dans une même vision pour la promotion de l'image du Maroc, cette stratégie devrait être axée sur une approche inclusive pour éviter la fragmentation des efforts et leur essoufflement.

Abstract

Hydrogen fuel production is a high-tech industry, a domain of technology entrepreneurship. One of the world priority areas is an automobile manufacturing, including production of hydrogen vehicles. Development of technology entrepreneurship in the field of hydrogen fuel production is a promising direction aimed at establishing a competitive advantage for Russian economy. The major results obtained as part of studies are as follows: 1) barriers hampering the development of technology entrepreneurship in the field of hydrogen fuel production for automotive transport were determined; 2) the most promising directions of hydrogen fuel production aimed at facilitating progress of technology entrepreneurship in this field were determined and described using the basic components of the theoretical model of technology entrepreneurship developed by I. Prodan.

Keywords: technology entrepreneurship, hydrogen fuel, green cars, a competitive technological advantage.

Introduction

In the face of natural resource deficiency every country feels a need to hasten the solutions for clean energy generation with alternative sources of energy.

At present in some countries alternative sources of energy already contribute to a quarter of all generated power. For instance, according to International Energy Agency (IEA, 2015) the leading positions in developing the domestic market of alternative sources of energy are taken by Island (IEA share – 25%), Denmark (20,6%), Portugal (18%), Spain (17,7%) and New Zeland (15,1%).

The most promising alternative fuel source is hydrogen. Its main advantage is eco-friendliness (water is the product of hydrogen combustion). In Russia hydrogen is applied in various industries (ERI RAS and ACRF, 2013), such as chemical and petrochemical industries, metallurgy, organic synthesis, food processing, aerospace industry, and glass industry. Potential applications of hydrogen are transport (internal combustion engine), power engineering (gas turbines), electro-chemical industry (fuel cells). The overall world production of hydrogen in 2013 was estimated to be 55-58 million tons, including 8% or 4.5 million tons of Russian share (Ogrel, 2014, p. 20-21). In the last years hydrogen production in Russia has undergone significant changes (Ogrel, 2014). Hydrogen production for chemical industry tends to decline gradually (from 80% to 70%), while its production in petrochemical industry increases significantly. Alongside with it, a triple increase in hydrogen demand is registered in glass industry in 2004-2013. According to Creon Energy (2015), in 2013 the major consumers of hydrogen were chemical industry (hydrogen consumption share – 68%), petrochemical industry (22%), while other industries using hydrogen in their production processes

accounted for only 10%. By 2020 a double increase in hydrogen consumption is projected in all aforementioned areas, though the use of hydrogen as a fuel in transport is projected to be low.

Use of hydrogen as primary or backup fuel in automobile industry opens prospects for its use as a major energy source. Nevertheless, currently, on the Russian market there are no companies, providing mass supply of hydrogen as a car fuel, though aerospace industry has experience in developing infrastructure for production, storage and transportation of liquid hydrogen (Malyshenko, 2010). Moreover, development of advanced Russian technologies in the automotive field (e.g. hydrogen motor fuel and fuel cells) is not encouraged.

On the other hand, hydrogen transport energetics is a constantly developing sector of international automobile concerns. For instance, Mercedes-Benz, Honda, DaimlerChrysler, General Motors, Ford, Toyota use 50 kW Ballard fuel cells to energize power units in civil transport (Ballard Power Systems Inc., 2015).

Therefore, by contrast with other developed countries Russia has not developed yet a concept for production and use of alternative motor fuels, which complicates development of home car manufacturing and motor building, as well as greening motor vehicles. Though playing an important role in the economic life, motor vehicles are some of the major factors responsible for air pollution due to the fact that currently transport fuels contain 95% of petrol and diesel fuel, made of oil products. Combustion products of oil fuels are harmful substances and greenhouse gases.

According to the Ministry of natural resources of Russian Federation (State Report, 2015), vehicle emissions slightly reduced from 2007 to 2014 (by 7, 1%) and amounted to 13621, 6 thousand tpa in 2014, or 43,8% of overall emissions by Russian fuel consumers. About 75% of emissions are carbon oxide (CO), about 11-12% is volatile organic compounds (VOC) and nitrogen oxides (NOx). Carbon dioxide emissions amounted to over 10554,6 thousand tpa by 2014, which is 30% of overall emissions in Russia. The total number of registered buses, cars and trucks increased by 24, 2% from 2010 to 2014 and amounted to 50500 thousand in 2014. On average, the car park annually increases by 5%. According to «Avtostat Info» LLC (Avtostat-info, 2015) the car park in Russia, as of 01.01.2016, increased significantly (by 6,3%), i.e. by 1 million 279,9 thousand, having reached 40 million 629,2 thousand.

The growth of vehicles will cause annual increase of vehicle emissions by 3-5% provided that the existing structure of the vehicle fleet does not change.

Assessment of environmental damages sheds a new light on the use of various fuels especially in metropolises, where emission reduction is an urgent problem. Adverse environment resulting from harmful activity of transport, rapid development of transport system and growth of vehicles, make it necessary to consider environmental issues when justifying the need for taking innovative decisions and choosing new technologies. In the context of environmental degradation in densely-populated areas and global warming, clean technologies become a top priority in developed countries, which have adopted state-run programs aimed at developing alternative sources of energy (e.g., EU countries, the USA, Japan, Great Britain). Alternative fuels have a range of advantages: complete combustion with a maximum heat release; minimum formation of toxic and corroding agents; convenient transporting and storage; applicability in different climate zones; relatively low cost of production. Thus, a radical way to reduce vehicle emissions is switching to hydrogen. Prospects of hydrogen energetics in transport depend, primarily, on successful development and production of fuel cells. Therefore, an urgent task is to determine the most promising directions for hydrogen fuel development which could compete with conventional motor fuels. Fuel cells allow converting the chemical energy of hydrogen into electricity with 60-70% efficiency output and its subsequent conversion into mechanical energy with over 85-90% efficiency output. As a result, the efficiency of the wheel can be about 50-65%. By contrast, efficiency output of the most powerful diesel car with a blown engine and intervening cooling does not exceed 50%, and efficiency output of a car running on

petroleum is 30% and less. In fuel cell cars hydrogen can be in two states: pressurized at 200-800 atm. or liquefied (at -253°C) (Bolonkin, 2013).

Obviously, development of hydrogen fuel production is viewed as one of the most promising technological advantage of the Russian Federation. In this regard, an urgent and important task of the state is to create an environment for technology entrepreneurship in the field of hydrogen fuel production for automotive transport. On the one hand, it will modify or radically change the process of hydrogen fuel production using unrealized technological capabilities of a new product or will allow manufacturing old products with a new source of materials supply or finding a new sales market for products due to reorganization of industry. On the other hand, development of the field under consideration depends on successful and up to date encouragement of technology entrepreneurship as a factor for increasing technological competitive advantages of Russian on the world market.

Thus, our research is aimed at determining pathways for developing components of the technology entrepreneurship model for successful hydrogen fuel production as a way to establish a competitive technological advantage of Russia. Next tasks must be completed: identify barriers, hampering development of technology entrepreneurship, assessing the basic elements of its model; determine the prospects for establishing technological competitive advantages of Russia in the field of hydrogen fuel production. In the course of study both a structural and functional method and a method of expert assessment were used.

The theoretical basis the research is concepts of Russian and international scientists on technology entrepreneurship, its structural modelling, and infrastructure development for hydrogen production. These conceptual approaches defined the research paradigm, reflected in the structure of the given article. Behavior of structural elements of technology entrepreneurship in the field of hydrogen fuel production was assessed with a model of technology entrepreneurship. The model allowed determining directions contributing to elimination of barriers which hamper development of technology entrepreneurship in the area of production under consideration.

Practical relevance of the research results lies in the fact that the specified directions for developing hydrogen fuel production will increase the number of consumers of green fuels and enhance the role of environmental factor when choosing systems of hydrogen fuel supply. The research results can be used by government agencies to work out measures for development and promotion of hydrogen industrial infrastructure for the transport system in the framework of the national program “Hydrogen energetics”.

Literature Review

An important contribution to the theory of technology entrepreneurship was made by researchers studying entrepreneurship as innovation (Schumpeter 1976). Some aspects of technology entrepreneurship are described by authors developing theories «based on new technologies of firms» (Shane and Venkataraman, 2003). Development models of technology entrepreneurship were studied by Brem (2011), Brazeal and Herbert (1999), Prodan (2007). The issues on developing hydrogen production infrastructure are discussed in scientific works of Lipman (2004), Levene, Mann, Margolis and Milbrandt (2005), Simbeck and Chang (2002), Amos (1998).

Despite a considerable body of works on certain sides of entrepreneurship, hydrogen production technologies, and their uses in manufacturing process, it must be noted that the issues of developing technology entrepreneurship in the field of hydrogen production infrastructure for transport and the role of government regulation of this production field are understudied.

Our research is driven by a necessity to identify barriers, hampering development of technology entrepreneurship in terms of developing hydrogen fuel market, as a promising competitive technological advantage of Russia and to determine strategic pathways for developing this field.

Results and discussion

Let us assess barriers and prospects for developing technology entrepreneurship in the field of hydrogen production.

It must be noted that technology entrepreneurship is defined as (The Canadian Academy of Engineering, 1998) innovative application of scientific and technical knowledge by one or several persons who start and operate a business and assume financial risks to achieve their vision and goals. Nowadays, some countries (Korea, Japan, the USA) consider investments in prospective research (i.e., in technologies of the future) and development of human assets to be their top-priority. Consequently, these countries invest more in R&D than other countries (2–3% of GDP). According to Global R&D Funding Forecast (R&D Magazine, 2010, p. 5) the USA spends 2,7%, Korea – 2,6%, Germany – 2,3%, Great Britain and Canada – 1,9%, Japan, Sweden and Israel 3,5–4,5% of GDP. Therefore, these countries have technological competitive advantages in future growth areas, e.g., green technologies, health, climate protection, power, mobility of human capital assets. In Russia, however, R&D expenses amount to only 1,3%. Thus, development of technology entrepreneurship requires substantial fund-raising into R&D from business. The main provision for increasing investment is de-risking. Analysis shows that there exist the following barriers for developing technology entrepreneurship in the field of hydrogen fuel production in Russia:

1. Absence of normative-technical and administrative legal base, specifying requirements for car manufacturers and fuel corporations.

2. Absence of infrastructure enabling car manufacturers to improve technology and launch on the market eco-friendlier cars.

3. Unstable economic health of the Russian car industry, experiencing financial losses in a down economy.

4. Unwillingness of native consumers to buy Russian cars.

5. Unwillingness of investors to deal with start-ups.

Apart from the above specified barriers, influencing manufacturers' and investors' performance, it is necessary to know end-consumers' opinion. In this regard, potential end-consumers of hydrogen cars in Russia were questioned. The next results were obtained: about 70% of respondents acknowledge the advantage of using hydrogen cars as compared to cars running on petroleum and diesel fuel. More than 50 % of respondents expressed their willingness to buy a hydrogen car, if it is to be sold at a reasonable price. The respondents also pointed absence of infrastructure as a factor hampering a large-scale use of hydrogen fuel.

To identify prospects for developing technology entrepreneurship in the field of hydrogen fuel production in Russia, let us present it as a logic chain considering basic components of the theoretical model developed by Prodan (2007).

Let us consider the entrepreneur, involved in hydrogen fuel production. Firstly, he/she must have a degree in both Engineering and the Humanities. Currently, most Russians have an opportunity to simultaneously enroll for two degrees, as well as to self-study. Equally important for a first-time entrepreneur is his/her background, because living environment and family traditions markedly affect he/she way of thinking and action when doing business. Entrepreneurial activity also requires skills to identify other people's necessities, quickly establish contacts and promptly respond to ongoing changes. Another valuable characteristic of an entrepreneur is team-building skills.

The next component of the technology entrepreneurship model is a university. Universities are basic producers of young and ambitious innovators. Besides, universities, generally, become the first and

sole base for most start-ups. Today, the largest Russian universities provide an opportunity for first-time entrepreneurs to manifest him / herself, creating business incubators, holding contests of innovative and business projects.

Although business incubators can be set up by different establishers and guided by different principles, including a commercial base, generally, the next scheme is used: the key founder of a business incubator is a university; a business incubator is set up to facilitate establishing spin-off companies, commoditizing the results of intellectual activity of the university teaching staff and students (Lendner and Dowling, 2007); the legal status of a business incubator is a non-profit partnership. This scheme is usually employed to set up business incubators in Russia within the framework of competitions held in accordance with the government initiatives, particularly, Decree of the Russian Government № 219 of April, 9th, 2010. Let us consider the research made by Rogova (2014), assessing the efficiency of technological transfer via business incubators. The study considers only business incubators set up by universities. Let us describe the author's methodology. Forty one questionnaires were distributed; twenty seven were answered, although in most questionnaires the managers did not answer all questions. The data were obtained in business incubators located in eight Russian cities. Most respondents were from Moscow and St. Petersburg, while some respondents were polled in Nizhniy Novgorod, Saratov, Krasnodar, Chelyabinsk, Tomsk and Novosibirsk. The results obtained are as follows. Firstly, assessment of efficiency (survival criterion) showed that six business incubators are efficient. Secondly, all business incubators present themselves as non-profit organizations, which is conditioned by particularities of Russian legislation. It also explains venture capitalists reluctance to invest in business incubators. Thirdly, most business incubators are not specialized, which allows mitigating commercial risks. On the other hand, it does not provide sustainable transfer of knowledge and technology, which are considered to be the key strength of engineering universities. Moreover, irrespective of the university specialization, most residents of their business incubators develop IT-projects. It is reasonable because such projects do not require substantial investment and special equipment. However, innovativeness of these projects can be low. Business-incubators in Russia (over 300) are relatively young. Business-incubators in Russia learnt to support start-ups, but are not yet efficient instruments of technology transfer.

High-technology production can be financed in different ways. Firstly, a grant can be obtained from different state and non-state funds. It is considered to be the most flexible method for project development. Secondly, a loan can be borrowed from a bank. Despite high risks, there are now various programs supporting small and medium businesses. In Russia there is also an efficient instrument for financial backing of technological entrepreneurship. Finances can be obtained both at the initial stages, when entrepreneurs have only a though-out plan, and later, when they have developed a project.

Prior to dealing with investors it is necessary to study the market and companies specializing in the same field. It must be noted that the major players on the hydrogen fuel market in Russia are enterprises which produce and consume hydrogen for their process requirements. There are also companies producing hydrogen for selling it on the target market (mostly as hydrogen peroxide, used in medicine). However, on the Russian market there are no companies producing hydrogen fuel, as well as there are no pre-conditions for setting up any companies of the kind in the nearest future. If any companies producing hydrogen fuel were set up, hydrogen could be supplied by Russian large chemical enterprises. These enterprises have a proven technology of producing clean and cheap hydrogen.

Another important component of the model is a state, initiating hydrogen fuel production. To support start-ups a large-scale project «Special economic zones (SEZ)» was launched in Russia in 2006. There are 18 zones on the territory of the Russian Federation so far. The administration company of each zone provides help to its residents at every stage of a project implementation. There are three types of special economic zones: industrial, innovative and tourist. Let us consider assistance lent by industrial and innovative zones to their residents. Industrial zones provide residents with necessary technologies and equipment, allot production areas, and provide telecommunication services and energy supply. Whereas, for innovative zones IT-services are provided in addition to the above

mentioned services. To become a resident of a special economic zone it is necessary to undergo a selection procedure. Firstly, you must apply on-line to acquire residency status, and submit a business plan and all necessary papers. After the application processing and its approval a project is to be defended before the Supervisory Board, and before the Expert Board. In case of its approval a trilateral agreement is made between a start-up, Ministry for Economic Development and a special economic zone.

Another way to obtain support is to collaborate with state-run corporations. Particularly, to produce hydrogen fuel it is necessary to cooperate with such organizations as Rosnanotech, Rostech and Rosatom. These corporations actively cooperate with small innovative businesses.

Assessment of elements of the technology entrepreneurship model in Russia designed for hydrogen fuel production showed that, in general, conditions for development have been created. Currently, some technologies for producing hydrogen fuels in Russia are being tested in laboratories, and some have already been mastered (e.g., electrochemical, chemical and physical). Moreover, conditions for developing R&D have been set, which enable catching up with rapidly developing world innovative technologies. Consequently, it is necessary to determine basic directions for developing a model of technology entrepreneurship in Russia in the field of hydrogen fuel production, namely, developing state policy in terms of hydrogen technologies. The policy will be intended to integrate national institutes and enterprises into the world market of hydrogen technologies. Thus, a national program on developing hydrogen energetics is required concerned with infrastructure development of hydrogen production for transport. The implementation of the program will include the following: creating manufacturing and storage infrastructure ensuring switching to liquefied hydrogen to power cars; developing new methods for producing hydrogen used as a fuel for large-scale consumption; promoting Russian technologies in the field of hydrogen fuel production for hydrogen cars; large-scale production of cars powered by hydrogen; developing a network of fuel filling stations; successful competition of hydrogen cars, i.e. production of cheap, high-temperature fuel cells; developing facilities for long-storage of hydrogen; production of different kinds of hydrogen vehicles. The program must also include a state target financing of fundamental and applied research and developments in the field of hydrogen production. Obviously, the program aimed at encouraging non-state companies invest in developing Russian hydrogen industry must be supplemented with a range of regulations, able to protect property rights and coordinate relationships of the agents of the hydrogen fuel market and quality of fuel.

Conclusion

A competitive technological advantage of Russia stems from mastering technologies for creating energy-efficient engines, engines for transport systems and other hydrogen technologies essential for Russian economy. It requires the establishment and implementation of a mechanism for developing hydrogen energetics including enterprises for producing hydrogen fuel, fuel cells and vehicles powered by hydrogen fuel.

Therefore, the mechanism for developing hydrogen energetics must be presented in the national program “Hydrogen energetics”. Let us consider its basic characteristics. Firstly, we need a national program, developed and implemented at the initiative and under the supervision of the President of the Russian Federation, approved by the Federal law, with guaranteed allocation of resources, and state control over efficient use of the resources. Secondly, the program must be complex. It must involve fundamental research on key problems; applied research, design and development activities on production, storage, transportation, and use of hydrogen and fuel cells in different fields, and their safety; a total of innovative projects aimed at mastering hydrogen production, production and maintenance of fuel cells; a total of support subsystems, mostly, a subsystem for managing implementation of the program and coordination of its participants’ activities, i.e., customers, research supervisors and realizers; regional and municipal bodies, interested in the implementation of the program and its large projects (including facilities for pilot testing of the program); customers, scientific and Executive Heads (international level – joint programs of interested CIS member states,

as well as bilateral or multilateral programs and projects with the countries outside CIS – the EU, China, India, the USA, Japan, etc.). Implementation of the program requires establishing a management company, and, in the long term, establishing an international strategic technological alliance or an international consortium. Thirdly, development and implementation of the program must be based on innovative partnership of government, science and business. The state must be responsible for developing a long-term strategy and a program, upfront investments in large research and innovative projects, providing fiscal and customs incentives for participants of the program, organizing international cooperation, protecting intellectual property, stimulating inventors, and patenting. The academic community — Russian Academy of Science, university scientists, civic academies, research and design organizations must build creative teams, including scientists and students from universities, able to develop competitive, advanced technological processes and facilities necessary for projects implementation. Large and small companies must monitor and develop new promising markets, actively participate in commercialization of new ideas, their innovative development, finance development and application of hydrogen technologies. Fourthly, the programs must be financed from different sources, meeting the requirements of modern pioneering market economy. A national innovative-investment fund might be established, accumulating budgetary resources allocated to the program and non-budgetary foundations, private companies, as well as funds raised through the stock-exchange market issuing and allotting shares of the fund or management companies. We also need venture funds supporting small and medium enterprises developing hydrogen energetics in regions. Fifthly, we need legal and regulatory bodies for development and implementation of the program, passage of federal law and other regulations; development and passage of the federal law on the national program "Hydrogen energetics", regulating the order of development and implementation of the national program, as well as the mechanism of its financing, government support and implementation; Decrees of the President of Russia and RF Government Decrees, regulating the order of development, implementation and government support of the program and projects; interstate agreements on developing and implementation of international programs and projects. Development and implementation of the national innovative hydrogen program will ensure practicing the mechanism of state influence on key directions of innovative breakthrough.

A large-scale application of hydrogen as an alternative energy resource is possible only under developing technology entrepreneurship in the field of hydrogen fuel production, able to provide Russia and other countries with cheap and clean energy. Development and implementation of the national program "Hydrogen energetics" will, on the one hand, allow utilizing hydrogen use in various industries. On the other hand, it will attract foreign investments able to change the structure of hydrogen production in Russia, namely, to build enterprises for producing hydrogen fuel, industrial installations and vehicles.

Romania: did it integrate or not?

Author full name: Florescu Ioana Cristina, Affiliation: Academy of Economic Studies, City: Bucharest, Country: Romania, E-mail address: ioanaflorescu2001@yahoo.com

Abstract

Through economic integration we are referring to a complex process, characteristic to the contemporary step of society development which consists in essence in intensifying the interdependence among different states, process which is conditioned by an assemble of factors of which an important part is the technical-scientific revolution.
This concept is best seen in the European Union out of which Romania is a member of since January the 1st 2007. In this article I want to analyze if Romania since entering the European Union did integrate on an economical level or not by comparing a series of the country's indicators to the ones in some developed member states. If not I will identify the problems Romania has and propose several solutions in order to achieve this faster.

Keywords: economic integration, European Union

Introduction

Extending the European integration means geographical extension (or vertical integration) and consists in new members adhering to the European Economic Community (EEC). Under this aspect the integration process took place in five successive waves of adherence, the geographical integration steps being indicated below:

- The founding members: 1957 – Belgium, France, Germany, Italy, Luxembourg and Netherlands;
- The first extension: 1973 – Denmark, Ireland, Great Britain;
- The second extension: 1981 – Greece;
- The third extension: 1986 – Portugal, Spain;
- The fourth extension: 1995 – Finland, Sweden, Austria;
- The fifth extension: 2004 – Cyprus, Czech, Estonia, Latvia, Lithuania, Malta, Poland, Slovakia, Slovenia, Hungary;
- The sixth extension: 2007 – Bulgaria, Romania;
- The seventh extension: 2013 – Croatia.

According to the report made by the National Prognosis Commission (2003) the process of in depth European integration (or vertical integration) began in 1950s and considers the following aspects:

- The progressive increase of the common objectives on which the Member States decide to realize together by extending the common policies areas;
- Enforcing the supranational character of the Community through the extensive use of the majority vote system (instead of the one existing on the

Council level based on unanimity), through which there are represented the national interests of each Member State, also by enforcing the role of the European Parliament (where are directly represented the European citizens)

- Through economic integration we can refer to a complex process which is characteristic to the contemporary step of society development which consists of in the intensification of the interdependencies amongst different states, process which is conditioned by an ensemble of economic factors.

B. Balassa (1961) considers the economic integration as process and a situation, as a set of measures to made in order to abolish discrimination between economic units belonging to different participating countries, assuming the absence of any form of discrimination between the respective national economies. By the same author, the total economic integration, requires monetary, fiscal, social unification of the countercyclical policy and requires the establishment of a supranational authority, whose decisions must be binding for the Member States.

J. Csillaghy (1965) deems the economic integration as the entry of an additional entity into an economic grouping, in a particular economic system and highlights the fact that it is quite difficult to achieve the integration of two different economic systems and maintaining the contradictory characteristics of each of them.

The economic integration is a high level of economic exchanges. The social integration represents the unification process from the masses, to specific groups of elites. The political integration has a variety of phenomena, including international decisions, similar attitudes among Member States.

The economic integration involves removing economic banks of two or more countries, barriers which in turn can be defined as representing any obstacles that distorts the mobility of the production factors. The European experience shows that the efforts made in order to eliminate all economic barriers eliminate the distortion that occurs at the level of single markets. These distortions are caused by differences in quality of infrastructure, the development level or the existence of industrial settlements that continue to manifest after removing economic barriers.

The stages of economic integration

1. Free Trade Zone

This is an area within which customs duties and quantitative restrictions to trade (quotas) were suppressed. The products can move freely and without quantitative restrictions inside the zone without paying customs duties when crossing internal borders of the area. The downside is that in such an area there exists the phenomenon of diversion of traffic goods for certain products originating in third countries merely to transit through the countries of the area who practice poor customs duties, to take advantage of the taxation regime on the border most favorable. To avoid these hijackings there was necessary a transition to the next stage of integration: Customs Union.

2. Customs Union

It talks about the customs union because when states have abolished customs duties and contingencies not only among themselves, but they also created a tariff (or external tariff) and a common commercial policy. The customs tariff is calculated by establishing the average of the tariffs applied in the custom territories that are covered by the Community. The first common customs tariff was established in 1968 and is reviewed periodically. To guarantee the free movement of goods and factors of production (capital, workers) only the passage to the third stage in terms of suppressing trade barriers is allowed.

3. Common Market

It speaks of the common market where goods, people, capital, services (transport, banking, insurance, stock exchanges) free movement in the market concerned - it evokes the 4 fundamental rights in the common market. Common market involves the application of rules and common legislation, in fiscal matters or in competition for example. It also assumes the existence of common sectoral policies, for example in agriculture or in transport.

A short description of the EU – Romania relationship

According to Daianu and Vranceanu (2002) the efforts made by the Romanian authorities for adhering at the European Union took place in an institutionalized framework since February 1993, the date of signing the Accession Agreement. In June 1995, Romania has officially submitted its application for membership. A first evaluation of the fulfillment of criteria was made by the EU in Agenda 2000, adopted in July 1997. In December 1999 the European Council decided to open the accession negotiations with the so-called "Helsinki group" consisting of 6 countries, amongst which was also Romania.

Regarding the adhering strategy, the most important event was adopting the Economic Strategy on the Medium term; in what concerns the compatibility with the EU regulations, the most important event was the beginning of negotiations regarding several chapters. Amongst a number of 31 negotiation chapters, Romania has finished the negotiations at 5 of them: small and medium companies, education and youth, knowledge and research, competition. it follows that in the beginning chapters to be negotiated relatively mild, leaving the thorny issues - such as agriculture - by a further approach.

The report of the European Commission from 2000 on Romania is critical on some aspects. Corruption is considered as being widespread, the pace of work of the legislature is low and the decisions made by the government lack coherence. Regarding the economic criteria, there were observed some positive results (a slight economic growth, an export growth, a fiscal deficit reduction); however, delaying the structural forms makes Romania not be seen as a functioning market economy. Regarding the adoption of the acquis communautaire, the report considers that Romania made some improvements to the legislation on competition, protection of

goods and copyright and transport. The limited progress – according to the report - was registered at the freedom of movement of goods, persons and capital, and social protection policies to fight unemployment; at the same time, more progress is needed in environment, agriculture, telecommunications, information technology and consumer protection.

The Romanian economy before integrating in the EU

According to the report made by the National Prognosis Commission from Romania (2006) the GDP per capita through the fact that it sums the result of the value added in all sectors – including the balance relations with foreign countries - reported to the number of population, represent without a doubt the most aggregate indicator for the economic development level of a country. This is often used in international comparisons, sometimes even to the point when they overlap.

Disregarding its valences that are in discussion for revealing the economic performance it should be noted, however, that this indicator suffers from some shortcomings. These are not related in such a great measure to the so its own attempt to evaluate from a single point of view a complex phenomenon, such as the economic development, but especially on account of its expression as a single currency when using official exchange rates, which doesn't consider the purchasing power of national currencies in the different states. As such, in order to mitigate the impact of these deficiencies, the gross domestic product was analyzed in US dollars purchasing power parity (PPP), which, with all the imperfections coming from the adjustment of exchange rates, helps to the sensitive increase of the inter-country comparability, and measuring its relevance, partially reflecting the standard image of life population.

Examining the hierarchy of states by the level of this indicator this reveals that the first place is owned by far the Luxembourg, with around 66 000 $ / person. Ireland occupies a surprising second place with about 40 000 $ / person (With over 40% of the EU25 average), in case of this state the speed through which the recovery of the gaps that existed two decades ago is remarkable (when it was listed, for example, below Italy in this regard). This fact could be explained by the high rate of economic growth (between 5 and 10% annually in the 1990-2005 period of time, rate of about 5 times higher than the EU 15 average). This is mainly supported by the main fiscal framework facilities and the massive influx for foreign investment. The big EU countries (UK, France, Germany, Italy, Spain) are focused on a range of indicator between 26-30 thousand $ /person., being noticed an approach of their level of development in the recent decades, with a special remark for Spain's rapid rise, due to Structural funds it drew from the EU.

Regarding Romania, the level of 8200 $ of GDP (in PPC) / person in 2005 represents less than one third of the EU 25average of $ 26.900. As seen from the data presented in Table 1, the Romanian development gaps revealed by this indicator remain significant both in relation to the developed countries of the EU (of 1/8 towards Luxembourg, 1/5 towards Ireland, 1/4 towards Austria, Denmark and the Netherlands, 1 / 3.5 compared to France and Germany, etc.) and in relation to

some Member States in Central and Eastern Europe (1 / 2.5 towards Slovenia and the Czech Republic, 1/2 towards Hungary and 1 / 1.5 towards Poland Baltic countries).

Table 1. The gap between the GDP of the EU Member States in 2005

Country	Gap	Country	Gap	Country	Gap
Luxembourg	8.1	France	3.5	Czech Republic	2.4
Ireland	4.9	Germany	3.5	Malta	2.3
Austria	3.9	Italy	3.4	Hungary	2.1
Denmark	3.9	Average EU25	3.3	Slovakia	1.8
Netherlands	3.9	Spain	3.2	Estonia	1.7
Belgium	3.8	Greece	2.8	Poland	1.6
United Kingdom	3.7	Cyprus	2.8	Lithuania	1.5
Finland	3.6	Slovenia	2.5	Latvia	3.6
Sweden	3.6	Portugal	2.4	ROMANIA	1.0

Reducing the gaps and the regional disparities of Romania in this regard depend, on the acceleration of the rate of the economic growth, accompanied by a balancing of growth factors, including in territorial profile, primarily by increasing the contribution of gross capital formation, supported by the domestic saving and the EU transfers. By achieving an average yearly rates of 6-7%, sustainable on the long-term, the calculations indicate that Romania could equal the European average GDP / capita in a time frame between two and three decades (assuming that the average rate of the annual growth for the whole EU25 not exceed 2 to 3%).

The Romanian economy after integration

According to Angelescu at all (2004) the perspectives of the Romanian economy after integration are based on the assumption that the government will continue its stabilization program and will increase the pace of the reform.

Operating as a single market with 28 countries, the EU is a major trading power in the world.
The EU economic policy aims at maintaining sustainable growth with the help of the investments made in transport, energy and research. Also, it tries to reduce the impact that future economic development might have on the environment.

Currently, the EU economy - taking into account the goods they produce and the services they provide (GDP) - is larger than the US economy: the EU's GDP in 2014 was 13,920,541 million dollars.

The dispersion of GDP per capita between the EU Member States remains quite surprising as we can see in Table 2.

Table 2. The GDP per capita for Europe

	Gross Domestic Product		
	2008	2009	2010
Luxembourg	279	266	271
Netherlands	134	132	133
Ireland	133	128	128
Denmark	125	123	127
Austria	124	125	126
Sweden	124	119	123
Belgium	116	118	119
Germany	116	116	118
Finland	119	115	115
United Kingdom	112	111	112
EU – 17	109	109	108
France	107	108	108

Norway	192	176	181
Switzerland	143	144	147
Island	124	118	111
Croatia	64	64	64
Turkey	47	46	49

Source: Data gathered from Eurostat, 2010

As in previous years, Luxembourg has the highest GDP per capita of the 32 countries, holding the detached leadership, with a GDP of two and a half times higher than the EU27 average and 6 times higher than the one of Bulgaria, which is

the poorest EU Member State in relation to this indicator. A special feature of the Luxembourg economy that explains, to some extent, the GDP per capita being high for this country, is that a large number of foreign residents are employed in Luxembourg and therefore they contribute to the country's GDP, while at the same time, they are not included in the resident population.

Netherlands ranks on the second place among the EU Member States, having a GDP with 33% higher than the EU-27 but it is overtaken by Norway and Switzerland, the European Free Trade Association States. Ireland maintains its position among the richest EU member states, but there is a clear downward trend between 2008 and 2010. This can be explained primarily by its nominal GDP growth, which fell by over 13% in that period.

Other EU Member States which in 2010 had a GDP per capita of at least 20% above the EU level were Denmark, Austria and Sweden. Belgium and Germany were about the same level, followed by Finland and the UK, while France is way ahead of Italy and Spain, the latter two having similar levels for several years.

Cyprus, which in 2010 had a GDP per capita slightly below the EU-27 average remained ahead of Greece, which has suffered from the economic crisis in 2010. Slovenia, Malta, Portugal and the Czech Republic are grouped around the level situated approximately of 20% below the EU27 average, well above the levels recorded by Slovakia, Hungary, Estonia, Poland and Croatia (one of the candidate countries for accession to the EU) which are situated at a level of about 40% below EU-27 average. Poland recorded a clear improvement in its relative position, while Lithuania and Latvia, on the other hand, report a decrease respective GDPs per capita between 2008 and 2010.

Romania and Bulgaria have GDPs per capita is slightly below 50% of the EU27 average.

Conclusion

This article tries to see if Romania did integrate in the European Union on an economical view. For this in my analysis I used as an indicator the GDP per capita for Romania which I compared to the same indicator in other countries from the European Union in the period before Romania's integration and after.

In conclusion I can state that this mechanism of economic integration included: creating a common economic space; free movement of factors of production when there is a common market; resource consumption along with maximum economic and social efficiency; achieving a customs union; implementation of common policies on economic, monetary, financial and social.

The expression "economic integration" can take different meanings according to the context wherein there is used. It may and express varying degrees of economic cooperation in a number of areas such as trade, labor mobility and capital payments, fiscal and monetary policy, social security and coordinate investment planning.

For Romania, joining the EU represented a strategic option having the acceptance of the political forces and the consent of the population's majority being considered the only way of medium and long-term development, in accordance with the national interests and objectives of the trends of globalization of the world's economy, carrying a multitude of costs that are not always accompanied by benefits. Even though at a macroeconomic level the evaluations regarding the financial implications of U.E. accession, theoretically, are strongly positive, however, judging at a microeconomic level this "gains" might, especially immediately after accession, be low, show loss or the impact could be almost zero or insignificant. Romania, through its economic complementarities, history, tradition and spirituality, through its geographical position belongs to the European area. Hence its firm option to join in 2007 at the economic and social structures of the European Union.

From what I observed Romania is still in process of integrating. Although now it is a member of the European Union, this country still has to adhere to the Shengen space and to adopt the euro as its national currency and work on absorbing more structural funds. Now the funding opportunities from both sources: national and international are insufficient used. These funds can be used to further develop the industry, the research domain, the transportation and the agriculture.

Abstract

In addressing social and economic demands more efficiently in the current economic environment, many governments are currently promoting a collaborative effort between the government, social organisations and the private sector in providing social services. In fostering the public-private partnerships, there is a need for an assesment tool for the private sector as well as the goverment to assess the social impact delivered by the social organisations. The social impact assessment tool can be used by the private sector in making their funding decisions, such as the amount of funds, selecting social organisation or portfolio of social organsiations and monitoring the social impact delivered. This study proposes a mixed method approach by integrating financial and non-financial measures in assessing the social initiatives performance assessment of the social organizations. The assessment approach contributes; (1) provide opportunities for the social organisations to demonstrate their accountability in delivering their social services and (2) provide performance management tool to the management of the entity in identifying the component to be strengthened in improving the delivery of their social impact and (3) used by the private sector and government in making their funding decisions, such as the amount of funds, selecting social organisation or portfolio of social organisations and monitoring the social impact delivered. Overall, the social initiatives performance assessment can potentially be a very useful tool to heighten social progress by creating a space for innovation in terms of positioning public services that meets the needs of the local society, as opposed to centralised governmental public policies.

Keywords: Social Impact, Social Services, Accountability, Public-private Partnerships

1. Introduction

The provision of various types of social services such as healthcare, social care, transport and waste collection are crucial for effective functioning of any communities. In many countries, social services have traditionally been provided by the government. However, the current challenging economic environment reduces the availability of funds and sustainability of organisations involved in the provision of social services. In response to this, many governments are finding new and more efficient means of providing these services. In this context, the Malaysian government has recently launched a pilot project, the *Berbudi Berganda Social Impact Innovation Challenge,* where social organisations were invited to propose fresh solutions for social issues in three areas: Youth Unemployment, Homelessness and Elderly Care (www.kualalumpurpost.net). The focus on social organisations is also in line with the growing interest globally (Chew & Lyon, 2012) in turning to these organisations or also known as non-profit organisations (NPO) as these organisations are already providing a variety of public services. An added advantage of these organisations is their

greater proximity to the issues on ground, making them a valuable repository of information and solutions, as opposed to centralised governmental public policies.

NPOs are formed not for making profits but rather to create social impact. Social impact can generally be defined as specific outcomes that are focused on reducing or eliminating unfavourable conditions in order to improve beneficiaries' economic standards of living (Kroeger & Weber, 2015; Martin & Osberg, 2007; Westall, 2009). These definitions highlight two important points. First, the current challenging economic environment has increased the issue on sustainability among the NPOs due to diminishing funding from traditional sources and increased competition for these scarce resources (e.g. Chew & Lyon, 2012 and Jiao, 2011). While these organisations can provide a new paradigm in delivering public services on behalf of the government, they need to be facilitated in terms of funding. In raising the source for social financing, the Malaysian government is promoting a collaborative efforts between the government, social organisations and the private sector. The second important point is the need for an assesment tool for the private sector as well as the goverment to assess the social impact delivered by the social organisations. The social impact assessment tool can be used by the private sector in making their funding decisions, such as the amount of funds, selecting social organisation or portfolio of social organsiations and monitoring the social impact delivered.

Currently, there is an array of approaches being adopted by social organisations in measuring their social impact (Arvidson & Lyon, 2014), ranging from pure quantitative measures such as Social Return on Investment and Balanced Scorecards to pure qualitative measures through narratives reporting on how the NPOs have delivered their purpose or mission and the benefits provided to the beneficiaries. While quantitative measures provide very objective measures, the need to monetise organisational outputs and outcomes may pose some challenges as some outputs and outcomes of social organisations may not be traded in a marketplace. In addition, the efforts and costs spend on data collection for these measures may outweigh the expected benefits. On the other hand, pure qualitative measures may lead to opportunistic reporting by the organisations where good outputs and outcomes are exaggerated to influence the relevant stakeholders with consequent negative effects on the reliability and relevance of the information reported. Based on these argument, this paper propose a mix approach for measuring social impact by social organisations that can facilitate them to discharge their accountability as well as meets the decision needs of the private sectors and other stakeholders.

2. Overview of Non-profit Organisations in Malaysia

In Malaysia, NPOs comprised of organisations that are either charitable organisations or societies. There are two main regulatory bodies governing the NPOs, the Companies Commission of Malaysia (CCM) and the Registry of Societies (ROS). NPOs with revenue of more than RM1 million can be registered as companies limited by guarantee and must be registered with the CCM and is held accountable by the *Companies Act* of 1965. For NPOs with revenue less than RM1 million, they must be registered with the ROS, within the Ministry of Home Affairs, and are held accountable by the Societies Act of 1966. NPOs in Malaysia have been classified into 14 broad categories, reflecting the type of social services provided: (1) religious, (2) welfare, (3) social and recreation, (4) women, (5) culture, (6) mutual benefit societies, (7) trade associations, (8) youth, (9) disable (10) education, (11) political, (12) employment associations, (13) general, and (14) others. The Malaysian government is promoting a collaborative effort between the government, social organisations and the private sector. The proposed collaboration can be summarised in Figure 1 below.

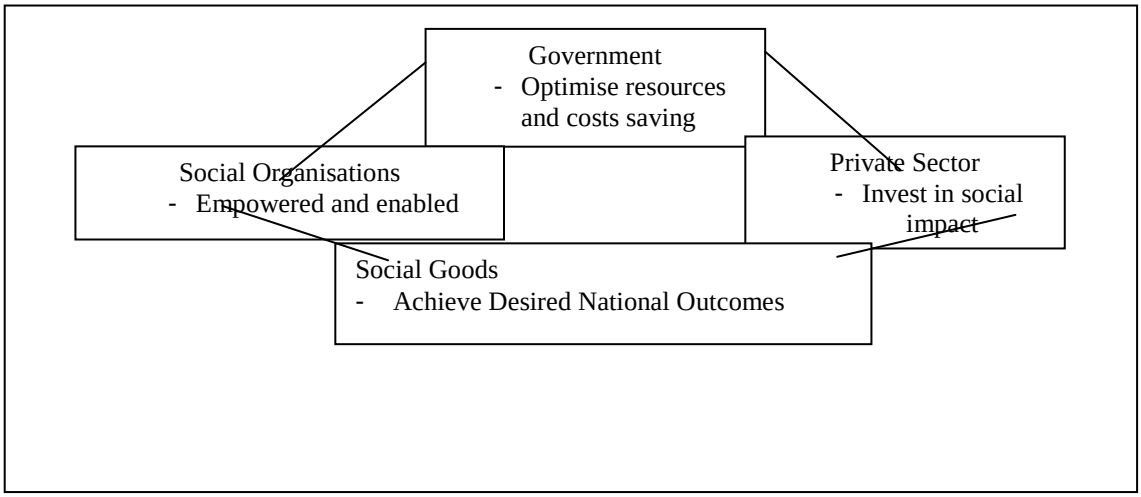

Figure 1: Public-private Partership (adapted: Agensi Inovasi Malaysia, 2014)

3. Social Impact

Resource providers for NPOs are more concerned with the NPOs demonstrating their effectiveness in fulfilling their social objectives. This indicates that resource providers place higher trusts on effective NPOs because these NPOs are expected to have higher accountability and deliver higher quality social services (Ebrahim, 2003; O Berg and Månsson, 2011). A large body of literature on NPOs posits that organisational effectiveness in NPOs is associated with goal attainment, i.e. the ability of the organisation to fulfil its mission (Helmig et al., 2014; Herman & Renz, 1998; Herman & Renz, 2008; Lecy et al., 2012). Epstein and McFarlan (2011) expand the definition of non-profit effectiveness to integrate the delivery of social mission and obtained maximum social impact from expenditures incurred. This definition highlights two important elements. First, social impact refers to "the future consequences of current or proposed actions, which are related to individuals, organisations and social macro-systems". The "future consequences of the actions" refers to the benefits given to the organisation's targeted beneficiaries as a result of the NPO outcomes (Epstein and McFarlan, 2011). For example, in the case of Tsunami aid (2006) – "*RM9.84 million was disbursed for boat repair and purchase of fishing nets, outboard motors and boats but this equipment were not used by the fishermen because they need to have certain skills to operate the equipment"*. In this case, the mission of the NPO is accomplished when the NPO provides fishing equipments to the fishermen (outcome), however, there is no impact from the outcome because the fishing equipments cannot be used. Second, "*obtaining maximum social impact from the expenditures*" refers to the NPOs ability to manage their resources efficiently. This in turn suggests that efficiency is a subset of effectiveness (Epstein & McFarlan, 2011, Helmig et al., 2014 and Lecy et al., 2012). Consistent with this argument, Parsons (2003) defines efficiency as the extent to which NPO devotes its resources in achieving the organisation's mission. Accordingly, Epstein & McFarlan (2011) argue that efficiency is about maximising the returns from the resources, in particular, donations that should be spent specifically for the cause it is intended. Overall, the literature suggests that efficiency refers to how well organisational resources such as donations and grants received are spent towards making an impact on the beneficiaries.

4. Methodology

4.1 Sample and Data Collection

Data for this study was collected from 12 entities that won the capacity building incubation awards of the *Berbudi Berganda Social Impact Innovation Challenge* organised by the Agensi Inovasi Malaysia. The challenge was launched on 1 October 2014. The incubation period was from

January 2015 to May 2015. The main aim of this challenge is to set the foundation for the creation of social groups that produce greater social impact through the delivery of their social mission. Data were collected mainly through partially structured interviews with the key decision-makers of the 12 entities. In some instances and where available, data were also collected based on the review of their annual reports, business proposals and other relevant documents.

4.2 Social Impact Measurement

This study proposes a mixed method approach by integrating financial and non-financial measures. Following Tuckman & Chang (1991), this study considers financial measures as an objective performance measure and it also captures the implicit intent of survival by the NPOs. Tuckman & Chang (1991) further argue that most NPOs attempt to continue meeting its objectives when a financial shock, such as an economic downturn or the loss of a major donor occurs. They identify these organisations as financially healthy while those not able to avoid curtailing their programs and/or services during a financial shock as financially vulnerable. However, due to the limited period of the research and the initial stages of most of the projects engaged by the entities, this study does not include these measures.

The integrated measure in this study is referred to as organisational effectiveness. In general, effectiveness refers to how an organisation successfully achieves its social mission (Herman and Renz, 2008; Spar and Dail, 2002; Sowa et. al, 2004). Effectiveness also incorporates the notion of efficiency, which means spending money wisely and producing measurable results (Andrews & Entwistle, 2013; Helmig et al., 2014). As such, efficiency can be argued to be a subset of effectiveness and in turn infers that organisational effectiveness is an important element in achieving social missions economically (Helmig et al., 2014; Lecy et al., 2012).

The non-financial measures incorporate five main components: input, activities, output, outcomes and impact. These components are summarised in Table 1 below:-

Table 1: Organisational Effectiveness Based on Non-Financial Measures

Inputs	Inputs are all key tangibles and intangibles that are brought into the organization to enable it to perform its tasks. Tangibles: example - cash, personnel, equipment etc. Intangibles: example-mission statement and strategy.	***Outcomes***	The specific change in behaviours and individuals affected by the delivery of these services and products. Example - for a secondary school, outcomes would be such items as alumni outperforming in college beyond what would be indicated by their initial test scores and achievements.
Activities	All specific programmes and tasks that the organization undertakes. Example - fundraising events, social entrepreneur activities such as selling cookies, set up stalls, etc.	***Impact***	Are there benefits to the communities and society as a whole as a result of these outcomes? Example - do our alumni take on important community leadership roles?
Output	Outputs are tangible and intangible products and services delivered as a result of the organization's activities. Example - for a school, it might be the number of graduates (tangible) and type and quality of college placements (intangible).		

4.3 Scoring Organisational Effectiveness

The main purpose of the scoring is to facilitate identification of emerging themes from the organisational effectiveness assessment. First, input is defined as how well the social organisations acquire their resources in order to generate social values for a particular social objective (Lee & Nowell, 2015). Therefore, it focusses on the acquisition of resources both in terms of monetary and non-monetary values. As highlighted by past studies (Berman, 2006; Median-Borja & Triantis, 2007), the input for this study can be summarised into five components:- (1) monetary resources such as grants and donations; (2) staffing and volunteers; (3) mission statements, (4) facilities such as space and trainers and (5) equipment such as ovens and computers. Thus, if the social organisation met all of the five components, this means that the input is sufficient.

Next, the activities under the social programmes are grouped and properly planned so that they are aligned with the social mission of the organisation (Epstein et. al, 2011). The activities of the social organisation consists of three main items:- (1) a list of activities that have intended impacts; (2) marketing strategies to promote the activities (3) a list of targeted participants. If the social organisations have all the items listsed in their activies, it shows that their activities are sufficient, i.e. the success of their activities is portrayed in the output.

The output measures whether the activities of the social organisations achieved the intended targets. The measurement is based on quantitative measures and addresses the number of people that has been served and the number of services that has been offered (Moxham, 2009; Epstein et. al, 2011). For instance, the number of homelessness participating in the programs offered.

The direct results from the output are referred to as outcome. It is a behavioural and environmental change of the target participants caused by the delivery of the social services (Epstein et. al, 2011; Rossi, Lipsey & Freemen, 2004). It measures the success of the activities or programmes in terms of any changes or improvements in the participants' lives. This included securing new jobs and set up new homes. Similarly, outcome is also measured by quantitative in terms of percentage (%), for example, the number of homelessness who have secured jobs.

Finally, results from the outcomes that benefits the society as a whole for a long term effect is called social impact. In other words, it measures the quality of the services given by the social organisations and therefore, it relates to customers' satisfaction (Lee and Nowell, 2015). Additionally, impact in this aspect concerns positive changes in the status of the participants. Thus, this study focusses on the quantitative measurement such as the reduction in the number of homelessness.

Scoring Organisational Effectiveness

Non-financial Measures	Descriptions	Score
Input	**Not available** **met only two components and below*	0
	Available but not sufficient **met three to four components*	1
	Sufficient **met all the five components*	2
Activities	**Not available** **none of the items*	0
	Available but not sufficient **has one to two items*	1
	Sufficient **has all the three items*	2
Output	**Below average delivery** * delivered between 0% to 40%	0

	Average delivery **delivered between 41% to 70%*	1
	Optimum delivery *******delivered between 71% to 100%*	2
Outcome	**Not fulfilled** **fulfilled between 0% to 40%*	0
	To be fulfilled *******fulfilled between 41% to 70%*	1
	Fulfilled **fulfilled between 71% to 100%*	2
Impact	**Below average impact** ** impacted between 0% to 40%*	0
	Average impact ** impacted between 41% to 70%*	1
	Optimum impact ** impacted between 71% to 100%*	2

Based on the above scores, the average total score will be computed. The average total score is ranked as below:

Average Total Score	Rank
1.6 to 2.0	High
1.1 to 1.5	Medium
0 to 1.0	Low

4.4 Findings: Organisational Effectiveness of the 12 Entities

The findings on the organisational effectiveness for the 12 entities are presented in Tabel 2 below**.** The names of the entities are not revealed due to the proprietary nature of the information.

Table 2: Organisational Effectiveness of the 12 Entities

Entity	Inputs	Activities	Outputs	Outcomes	Potential Impacts	Average Total Score
1	2	1	2	1	2	1.6
2	2	2	2	2	2	2
3	2	1	1	0	2	1.2
4	2	2	2	2	1	1.8
5	2	1	1	0	1	1
6	2	2	1	1	1	1.4
7	2	1	1	1	2	1.4
8	2	2	1	0	2	1.4
9	2	2	1	1	1	1.4
10	2	2	1	0	1	1.2
11	2	2	1	1	1	1.4
12	2	2	2	1	1	1.6

Entity 1

The strength of this project is the collaborative efforts with other NPOs that contribute to the inputs of various resources currently available. However, some critical resources such as human capital and structural capital, i.e, all structures and processes needed by members of the projects in order to be productive and innovative to deliver their social mission. In addition, this project has insufficient marketing strategies – not publicised in the media, project not well known by public, probably due to the current capability of the project in order to increase the cash flow of the entity. Overall, the entity's project average total score is 1.6 and ranked high potential impacts even though it is still at an early stage.

Entity 2

This entity has strong network with other NPOs and private corporations in securing various resources. In addition, the entity has also embarked on several business activities to achieve its outcomes and enhance the potential social impact delivered. The average total score if this entity is 2.0 and ranked high with high potential impacts.

Entity 3

The main issue with this entity is capability in terms of human capital, social capital and structural capital. The current strength of this entity is the availability of a relatively high number of volunteers to facilitate the project to ensure that it remains viable. The entity's average total score is 1.2 and ranked medium even though the potential impacts are quite high.

Entity 4

The entity's strong network with various corporations has led them to be a credible social service provider. With this good reputation, the entity is able to attract volunteers and beneficiaries in facilitating the delivery of its social services. However, the potential social impact of this entity is low as it is highly dependent on public & corporate contributions. Except for this aspect, the entity's average total score is 1.8 and ranked high.

Entity 5

The main issue with this entity is capability in terms of structural capital, in particular the financial capital involved in attracting the beneficiaries is quite substantial relative to the potential impact. However, the establishment of a good networking with influential and knowledgeable volunteers is an added advantage for this entity. The entity's average total score is 1.0 and ranked low with low potential impacts.

Entity 6

The main challenge of this entity seems to be associated with the potential beneficiaries/youths with some social issues. This in turn reduces the potential outcomes and impacts of this project. In addition, the project is also very dependent on government fundings. However, the establishment of a good network with various government agencies is an added advantage. The entity's average total score is 1.4 and ranked medium with low potential impacts.

Entity 7

The main issue faced by this entity is that it is yet to fully embark on providing the social services to the beneficiaries. This is mainly due to its inability to source out for interested beneficiaries. In essence, the entity has the main issue with capability in terms of human, social and structural capitals. However, the entity has the potential impact of benefiting the local community as well as the relevant industry in Malaysia if it can be carried out successfully. Hence, the entity scores 2 for potential social impact but the entity's average total score is only 1.4 and ranked medium.

Entity 8

The entity faces substantial challenges in providing its' social impact – such as procurement for relevant resources, retention of beneficiaries and income generation through its business activities. The entity is currently single-handedly managed and operated. A strong leadership together with a highly committed staff is imperative in order for the entity to provide sustainable social

services. Overall, the entity has various capability issues. However, the social impact of this project will enable the beneficiaries to financially support their families, thereby reducing and eradicating unemployment and enhancing their current living standards. Hence, the social impact of this project is high even though the average total score is 1.4 and consequently ranked medium.

Entity 9

The entity is run by committed and paid members of the organisations. While the entity has the potential to grow, the social impact measurement with regards to reducing youth unemployment may take a longer period to measure. Hence, the entity scores only 1 for social impact but the average total score is 1.4 and ranked medium.

Entity 10

The entity faces issues of commitment by beneficiaries, specifically the selected homeless persons and the inability to provide data of outcomes achieved. The lack of various types of capabilities needed to ensure optimum delivery of services may contribute to the challenges faced by the entity. To date, the entity scores only 1 for social impact even though the average total score is 1.2 and consequently ranked medium.

Entity 11

The entity currently focuses on two beneficiaries. As such, it reduces the potential social impact the project can deliver given the availability of financial capital. Hence, the entity only scores 1 for social impact. However, the entity has the potential social impact of protecting the environment if it can be carried out successfully. The project average total score is 1.4 and ranked medium.

Entity 12

The entity is a well establish NPO and does not face any issues on sustainability as it has a strategic and proper planning to make sure it meets its mission and social impact. With the advantage of having a strong network, highly committed staff, participation of volunteers, skilled trainers, quality training modules and a large network of trainers, the entity possesses many strengths. As such, social services provided through training conducted for the unemployed, underprivileged youths could be carried out smoothly. However, the main challenge is to ensure the youths continue to participate in all the cycles. This reduces the potential impact of the service provided by this project. Hence, the entity only scores 1 for potential social impacts but the average total score is 1.6 and ranked high.

Findings: Emerging Themes

The above review provides evidence on the performance of the entities in achieving their social mission. However, the above findings are based on non-financial measures only due to inapplicability of the financial measures for this study.

Of the 12 entities, 4 entities score high for the average total score even though 2 of these entities only score 1 for the social impact measure. The 7 remaining entities score an average total score between 1.1 to 1.5 and ranked medium while 1 entity has an average total score of 1 and ranked low. Overall, the non-financial measures used in this study allow stakeholders to assess the various components that are interrelated with the delivery of social impacts to the society.

The measurement approach used and findings based on this approach have two main contributions:

- provide opportunities for the entities to demonstrate their accountability in delivering their social objectives, and
- provide performance management tool to the management of the entity in identifying the component to be strengthened in improving the delivery of their social impact,

While the above measurement approach has potential applicability in measuring the performance of non-profit organisations, there are some limitations. The qualitative nature of the non-financial measures provides opportunistic/creative reporting practices that can increase the ambiguity

and reduce the reliability of the information reported. Nevertheless, the measurement method adopted provides some information to relevant stakeholders in making their decisions.

5. Conclusions and Future Research Agenda

The main objective of this study is to examine the social impact measurement for NPOs that can provide relevant information needs to the various stakeholders. There are two main findings based on this study: (1) there are unique challenges with regards to the capability of entities in ensuring sustainability of their social impacts and (2) the social services delivered can potentially add value to the society as reflected in the social impact measurement results. This in turn has several implications: (1) indicates the need for policy makers to strategically support the capability building of this new innovative paradigm in delivering social services if the current status of public service delivery is to be alleviated and (2) increased understanding is required on social impact measurement and management for organisations providing social service directed toward social impact on society. One important justification for such understanding is how social impact measurement and management can be used to balance the demand of accountability by the resource providers and internal performance evaluation and strategy. Even though a mixed-method approach has been justified in this research, there is a need to examine further the various quantitative and qualitative measures as literature on the performance measurement of non-profit organisations highlighted the demand for these measures in providing meaningful information.

Acknowledgments

This study is funded by the Agensi Inovasi Malaysia, Prime Minister's Department, Government of Malaysia and Long Range Research Grant, Ministry of Education, Malaysia and Accounting Research Institute, Universiti Teknologi MARA. The authors are grateful for the cooperation given by all the entities throughout the research period. The authors would also like to thank the Agensi Inovasi Malaysia for permitting the use of their proprietary data in this study.

Abstract

As a Knowledge Intensive Business Services, companies engaged in Commercial Archaeology in Spain, a business sector, little known and little studied, emerged around the boom in civil engineering and the building sector and, like them, has been affected by the economic crisis. The aim of this work is, through a systematic review of the literature, analyze different methods of recognition and measurement of intangible assets applicable to archeology companies, that could contribute to raising the value of this kind of companies, as a tool to achieve sustainable management of these companies.

Keywords: knowledge Intensive Business Services; Intangible Asset Valuation, Sustainable Management.

1. Introduction, objectives and methodology.

Defined as certain highly innovative industrial services with high technological content, Knowledge Intensive Business Services (KIBS) are characterized by a heavy reliance on professional knowledge. They may also be primary sources of information and knowledge (reports, consulting, etc.), or use their skills to produce brokerage services for production processes of customers. They have become very important in terms of competitiveness by providing knowledge to businesses and a differential in its sector (Miles et al., 1995). The KIBS are companies that depend on knowledge or expertise of a specific (technical) discipline and provide intermediate products and services often based on knowledge (Escauriza et al., 2001).

As mentioned above, the main feature of KIBS is highly dependent on knowledge, therefore, much of the value of these companies will be their Intellectual Capital. For this work we rely on the definition by Steward on Intellectual Capital like intellectual material, knowledge, information, intellectual property and experience that can be used to create value (Steward, 1997).

Wealth and growth in the economy today are mainly attributable to Intellectual Capital as the resulting value of all intangible assets (Edvinsson and Malone, 1997) . There is an appreciation that knowledge, common constituent of most intangibles, is an important resource and a powerful factor of production. Intangible assets are non-monetary and without physical substance and have to be used in the production or supply of goods and services assets (García- Merino et al., 2010).

From among the Knowledge Intensive Business Services, companies engaged in the commercial management of Archeology can be considered. This is a business sector, little known and little studied, which emerged around the increase of civil engineering and the building sector in Spain. It has- just like the building sector- been affected by the economic crisis in Spain. At present, this sector is threatened by the lack of public investment and budgetary devaluation which have affected these services. The deadlock that the business model of commercial archeology is suffering due to the economic crisis, has caused its collapse. The decrease in volume of construction in both the public and private spheres involves reducing the number of archaeological interventions. Therefore, there is a need to pivot the view we have on the problem to solve, and how it should be done. In the current model of Spanish Archaeological Heritage management, archeology companies are one of the major players. The crisis in this sector endangers the preservation of our Archaeological Heritage, a nonrenewable good of high social value.

The research being carried out on this topic, is based on the premise that in order to reach a sustainable model of commercial archeology, one of the steps is to determine the value of output produced by archeology companies. To do this, the valuation of intangible assets (which are necessary for the execution of the activity and which generates the activity itself) present in this economic activity arises. The aim of this study is to do a preliminary analysis of a future deep work about different methods of recognition and measurement of intangible assets that could be applied to archeology companies as a contribution to raising the value of the companies engaged in this commercial sector as KIBS, for the sustainable management of this types of businesses.

2. Commercial archaeology in Spain.

Starting in the 1980s, a phenomenon of urban sprawl took place in Spain and saw with it the destruction of a large amount of Archaeological Heritage in cities. In order to protect, preserve and manage the assets of the country, the Spanish Historical Heritage Act was drawn up in 1985. This Act follows the European guidelines set by the European Convention for the Protection of Archaeological Heritage, signed in 1969 and ratified by Spain in 1975 (Querol, Martinez, 1996).

A decentralization process took place with the establishment of the democratic model in Spain which resulted in a State of Autonomies. Through this model, the responsibility for the Heritage management is delegated to the autonomous communities. Under a common legal framework, the Constitution of 1978, the Spanish Historical Heritage Act of 1985 and the relevant Statute of Autonomy, each region produces different heritage management models and publishes regulations that make for a diverse the legislative treatment of archaeological heritage in each Autonomous Community.

As a result of this regulatory change, a new demand around the sectors of civil engineering and construction is created associated with changes in land use promoted by different sectors: public, private or mixed. The enforcement of the laws of environmental and Historical / Cultural Heritage impact, which requires carrying out archaeological work, generates new economic activity.

The government is unable to fund this new demand for liberalization of its archaeological load floor, thus the archaeological activity moves to the business. As a result of this new landscape a number of liberal professionals and companies conducting archaeological emergency interventions have emerged; Conducting surveys, probing, overseeing extensive excavations and monitoring work which has transformed archeology - an activity that had strictly been within the scope of academic and public institutions (universities, museums, archaeological services councils and municipalities and other) - into a commercial activity.

Therefore, the rise of commercial archeology does not respond to institutional planning, but to an impromptu response to the ideological adoption of an Anglo-Saxon neo-liberal model which was a priority in the privatization of services by policy makers following the current vogue in Europe in the late 90s.

During the years of urban growth in Spain and above all with the real estate boom which took place in the country between 1998 and 2007 there was a significant increase in the number of self-employed professionals and companies dedicated to the management of Archaeological Heritage and to the direct implementation of archaeological rescue excavations, also known as “preventive archeology”. The transformation of a discipline such as archeology - which had emerged within the academy – into a business activity was made without planning and with little or no preparation of the new professional archaeologists nor the National and Local Administration technicians in business management.

The rise in entrepreneurship archeology took place in major Spanish cities and spanned 2000 to 2005. The first database of a nationwide survey on business Archaeology in Spanish territory (Parga-Dans, 2010) in 2008 it accounted for 273 companies.

At present the economic crisis has brought about the devaluation of archaeological work; primarily by reducing archaeological emergency measures and secondly by devaluating the budgets allocated to them. Generating this activity is ceasing to be profitable. The number of archeology companies has shrunk by 42% - according to preliminary results of the second national survey of archeology

companies presented by Parga-Dans PhD at the 19th Annual Congress of the European Association of Archaeologists held Year 2013 (Parga-Dans, 2013).

Thus, an emerging knowledge-generating business - such as commercial archeology - whose greatest differential is in the generating of knowledge and in the creation of highly qualified employment has been devastated by the economic crisis.

3. Generating knowledge: by-product or joint product archeology?

In commercial archeology, the product the customer wants is the favorable binding report of the authority responsible for culture in the Spanish management model of the archaeological heritage; so that the customer may start his work. This report is obtained after completion of the relevant archaeological interventions authorized by the local Administration, and the evaluation of the Scientific Report drafted by the technical managers responsible for different tasks performed by the archeology company. The product: the favorable binding report, and the by-product: the scientific report in which the knowledge generated is captured, are themselves intangibles. This is finally a product undervalued by the prospect of commercial archeology, however, it is an essential part of the activity. Knowledge generation, as part of the production process of commercial archeology, is a return to society as a whole, which partly offset the "loss" of a portion of its common Cultural Heritage for the benefit of a single promoter.

The term by-product has different meanings, in varying degrees, it often has negative connotations associated with the waste concept, or in the best case, it has a lesser value than the main product.

In this study, we prefer the definition of by-product or as in the Spanish Law 22/2011 of 28 July on waste and contaminated soils, "a substance or object resulting from a production process whose primary purpose is not the production of that substance or object can be considered as a waste by-product and not [...] if it fulfills the following conditions: (i) the safety of the substance or object will be will be later use, (ii) the substance or object can be used directly without having to undergo further processing other than normal industrial practice, (iii) the substance or object is produced as an integral part of a production process, and (iv) the subsequent use meets all relevant requirements relating to the products and the protection of human health and the environment, without producing general adverse impacts to human health or the environment. " State Official Newsletter in Spain (BOE) of July 29, 2011 (number 181).

The new data from surveys and archaeological excavations as traces of work are recorded after processing in a Scientific Report. This is the document where the knowledge generated is captured, thus it could be considered a by-product in the production process of commercial archeology. The customer of commercial archeology does not usually give importance, with few exceptions, to the generation of knowledge emerged as a by-product of this economic activity, considering that it does not generate value for the company. However, knowledge created following an archaeological excavation was established as the generating of an intangible value whose beneficiary is the whole of society; If these issue were valued by customers of commercial archeology it could improve their visibility.

Furthermore, we also consider the concept joint products referred to individual products, each with significant sales values, which are generated simultaneously from the same raw and / or manufacturing process whose basic characteristics are:

1. They have a physical relationship that requires a common simultaneous processing. The process of these products results in the processing of all other products simultaneously.

2. The manufacturing always has a point of separation arising separate products to be sold as such or be subjected to further processing.

3. None of the joint products is significantly greater in value than the other joint products.

In the case of commercial archeology, and taking into account the characteristics described above, it might be considered perhaps the generation of knowledge as a whole product, not as a by-product of the production process.

4. Intangible assets in commercial archeology: a review of valuation methods.

Currently, the economic value of the product generated by archeology companies does not follow criteria generated after a rigorous analysis of production costs but rather estimates up to each professional guidance based on prices set by different professional associations in the different Communities autonomous, when there.

Being the Commercial Archaeology a Knowledge Intensive Business Service, whose activity is based on professional knowledge, it is vital to add to the valuation of tangible costs the assessment of existing intangible assets in these businesses to determine the value of knowledge generation, joint product in the production process of commercial archaeological activity. To quantify economically the benefit of the knowledge generated to a company from archaeological interventions should be a priority to give new impetus to this type of asset management companies and contribute to its sustainable management.

Intellectual capital is becoming the resource of choice for creating wealth and its management has become a key task for business management and facilitating organizational learning and knowledge creation (Martin de Castro, Delgado-Verde, 2012). Knowledge assets and information are key to creating and maintaining a competitive advantage and a superior performance of an enterprise (Edvinsson and Malone, 1997).

In recent years, there have been numerous proposals for measuring the intellectual capital of a company, although it is a complex task.

There are two ways by which the valuation of intangible assets is performed:

1- Those whose objectives are based on management assessment which includes two activities: identifying intangibles and place them in a structured system and look for indicators that allow the proper development of such intangibles (ratios and non-monetary measures) and

2- Those intended to determine the financial valuation that aims to find the monetary value of such intangibles.

On the other hand, the methods of valuing intangible can be classified as being based on:

- Its costs: intangible is assessed in terms of the cost of acquisition, creation or maintenance. -The Market value: examines transactions (sales, acquisitions, licenses ...) that have been involved similar intangible assets for which prices are available for the operation.

-The Income: assessment of the ability to generate profits or income of an intangible asset. Another classification of methods is based on the tools in which it is based. So the methods are classified as:

- Direct: estimate the monetary value of intangible assets by identifying its components and once identified they are measured directly.

- Based on capitalization: Calculate the difference between the capitalized value of the company and the value in a stock market. This difference would be the total value of any intangible Company

- Based on the return of intangible assets: involves dividing the average pre-tax profits of a company over a given period by the average of intangible assets held. The result is the ROA of the company that can be compared to the average values of the sector.

- Based on the scorecard: the various components that make up the intangible assets of the company and indicators and indices which in turn report to a dashboard are generated are identified. Not seeking the monetary value of the assets but to assess its evolution in order to properly manage them.

5. Conclusions

After performing the different classifications of the valuation methods of intangible assets through the literature, we conclude that, for the assessment of intangible assets for KIBS such as Commercial Archaeology, may be more effective direct methods (DIC) those based on the Return (ROA) and methods based Dashboards (SC).

Direct methods (DIC) and those based on the Return (ROA) can be useful to make comparisons between companies in the sector and show the financial value of intangible assets, thus drawing the attention of the directors of companies archeology of these assets and their customers on the value of the service. In addition, models of financial valuation of intangibles facilitate their transfer to the accounting methods and thus help determine the actual cost of providing the service offered, which can contribute to the sustainability of these businesses.

Methods based on Dashboards (SC) may show a more complete and comprehensive situation of intangible assets in a company dedicated to Commercial Archaeology image. This can be especially useful to propose new management models for Commercial Archeology as a way to give new impetus to these businesses also contributing to the sustainability of the sector.

Development of Academic Staff´ Competencies

Ivana Cechova, University of Defence, Brno, Czech Republic, ivana.cechova@unob.cz
Radomir Saliger, University of Defence, Brno, Czech Republic, radomir.saliger@unob.cz

Abstract

The paper is focused on the development of academic staff' competencies, with emphasis on pedagogical and language skills. It is based on the outcomes of the project, "Innovation of the Master's Degree Program of the Faculty of Military Leadership". Different strategies were used to determine the academic staff´ needs, wants, strengths, and weaknesses in their teaching practice, with the emphasis on the teaching of foreign students.

Through the method of a questionnaire survey and subsequent data analysis, the authors suggest some recommendations and advice for academic staff in order to enhance their teaching skills in English. Thereafter, attention is focused on teaching experience in courses for academic staff, their evaluation, and future strategies.

Keywords: academic staff, professional education, pedagogical competencies, language competencies.

1 Introduction

Development of workers' skills and competencies is currently a very topical issue for experts and workers in all fields. The types of basic skills and competencies required in working life are changing all the time, which calls for further development of existing competencies.

The terms "skills" and "competencies" are used interchangeably. A competency can be understood as "the capability of applying or using knowledge, skills, abilities, behaviours, and personal characteristics to perform successfully critical work tasks, specific functions, or operate in a given role or position" (Dubois, 1993, Lucia & Lepsinger, 1999). Competencies or individual characteristics were recognized as "significant predictors of employee performance and success" (Lucia & Lepsinger, 1999, McClelland, 1973).

According to McClelland, competencies can be perceived as significant predictors of employee performance and success, and are equally as important as an individual's academic aptitude and knowledge content as indicated by tests scores or results (McClelland, 1973; Lucia & Lepsinger, 1999). A competency can be defined as the "capability of applying or using knowledge, skills, abilities, behaviours, and personal characteristics to successfully perform critical work tasks, specific functions, or operate in a given role or position" (Dubois, 1993; and Lucia & Lepsinger, 1999). Competencies are comprehended as "specific personal qualities related to effective and/or superior performance" (Boyatzis, 1982). They are common across many settings and situations, and "endure for some time" (Delamare Le Deist & Winterton, 2005).

Palan combines competence development with lifelong learning and argues that "lifelong learning is the only interconnected unit which enables diverse and numerous transitions between education and employment, and which provides the same qualifications and competence in various ways and at any time during the life" (Palan 2006).

Competence in communication, especially communication in foreign languages, belongs among the key competencies of the 21 century. Veteska claims that "Meaning of competence in the context of linguistics, can go even further, whether it is used in relation to the ability to work or perform part of the work competently, or in relation to behaviour (how one should behave in order to fulfil competently the tasks or perform the function") (Veteska, 2010).

Academic staff´ competencies include not only teamwork, career motivation, problem solving, trustworthiness and ethics, decision making, commitment to career, and communication, but also some specific skills oriented to this very specific profession. Education and training of academic staff form a part of everyday life in their workplace, college or university, and mainly take the form of non-formal and informal education. By the term 'education of academic staff', we understand that enhancing the level of their knowledge, expertise, skills, and competences is closely linked to the development plans of each university.

Eraut, Koklarova and Cech have conducted some studies vindicating the notion that education of academic staff primarily takes place at the workplace in the form of informal education (Eraut et al, 2000 Koklarova 2013 Cech 2014). This is due to the specificity of professional training of academic staff, which mainly includes direct contact with labour issues and processes. In the case of academic staff, the professional training includes all everyday activities, including collaboration and discussion with colleagues, preparation of individual lectures and lessons, scientific and expert activities, and teaching itself. A university teacher can be characterized by: high level of scholarly erudition, creation of scientific knowledge (ie. scientific research and research activities) and the passing on of this knowledge to the younger generation.

In today's competitive environment the only institutions, universities, and colleges which have a chance to stand and be attractive for prospective students, are those whose academic staff can prove the high quality of their teaching practice and are better prepared for performance of their profession. Holcner emphasizes the role of education not only of students, but academic staff as well (Holcner, 2010).

2 Professional education of academic staff

Cech and Koklarova have conducted research dealing with the acquisition of professional skills in different sectors; academic staff in tertiary education create one of the studied groups. The research proves the important role of the workplace in the development of professional competencies and skills of academic staff. The research outcomes prove that for academic staff of all age groups it is important to enhance their professional skills and competencies. Among the most significant methods mentioned are: working alongside more experienced colleagues; working with students; thinking about work and lessons from errors; working as part of a team; learning and teaching younger colleagues; and experience from previous work (Cech, Koklarova 2014, Cech, Chromy 2015).

The development of competencies of academic staff involved in teaching in an innovative study program of the Faculty of Military Leadership occurs in a project called "Innovation of the Master's Degree Program of the Faculty of Military Leadership". One of the project's objectives was focused on development of academic staff involved in teaching in this subject program. The main attention was focused not on the development of professional competencies in their respective disciplines but on the development of their teaching skills. The teacher/university professor is perceived in this project as the only person accountable for the relevance and quality of the teaching process which reflects the latest scientific findings, and for the development of the student's personality and fulfilment of the declared student learning outcomes (Holcner, 2015).

For every university, the development of the skills to teach special subjects in English represents a prerequisite of internationalization as one of the attributes of quality in higher education within the

European educational space. On the other hand, university graduates are expected to be fluent in at least one foreign language. The emphasis is on English language skills: listening, speaking, reading and writing. The university graduates must be able to present their ideas as well as the research outcomes in English, to participate in briefings, to take part in discussions, and to master terminology of their specialisations.

3 Pedagogical competencies

One of the most significant features of teaching at universities is the contradiction between professionalism and scientific erudition of most academic staff, and sometimes their "amateurism" in carrying out their main mission - the education of students of accredited study programs and participants in lifelong learning courses. During their career only some of them marginally studied or met the following subjects: psychology, andragogy, social education, philosophy of education, communications, and legal aspects of universities or their history. Lack of knowledge and skills in these fields is usually replaced by critical reflection of their own study experience, and the effectiveness of the university teachers they were taught by. Academic staff should be able to develop and hone their teaching skills. Generally, the competence comprises a set of knowledge, skills, abilities and attitudes, enabling the professional and personal development of an individual. The competence of academic staff can be understood as a precondition to perform a specific set of actions, in this case comprehensive educational activities, scientific research, and management duties at the university.

Academic staff of Faculty of Military Leadership, University of Defence strive to apply in their teaching practice not only deep knowledge of their specialisations but also pedagogical and didactic principles. For that reason, a course to enhance pedagogical competencies of academic staff was created, lasting two semesters, and whose participants were taught andragogy philosophy, psychology, sociology, law, history, education, military and social communication, and rhetoric. All participants were asked to fill in a short questionnaire during, and again at the end of the course, not only to assess the course but to give some advice, recommendation, or further information for the course teachers and managers. Among some of the questions were:

- Recommendations dealing with the study support in Moodle (scope, content, clarity).
- Recommendations on teaching (teaching itself, level of interactive teaching space for the exchange of experience).
- Did the course arouse your interest in the pedagogical issues? Specify.
- Usefulness of the course, topics for your teaching.

3.1 Questionnaire Outcomes

The course participants during the course answered a set of questions and assessed the course organization, study supports and materials, and particular topics. The participants of this course generally agreed that the course was well-managed, had sufficient space for mutual exchange of experience, ideas and knowledge from their own teaching practice.

Study supports and materials as well as presentations in Moodle were positively assessed by the course participants as understandable, clear and logically structured, interesting, useful, and enabling basic orientation in the issue. The theme of philosophy of education was judged by some participants as very complicated, with relatively large study text and a high amount of study supports. Only philosophy was assessed as quite complex and demanding.

The majority of presented topics aroused the interest of the course participants, who especially appreciated the suggestive content, appropriate form of management, and practical examples. A lot of the course participants perceived the teaching of teachers as inspiring them to improve their own educational work.

Usefulness of the course and topics was assessed by participants positively and they evaluated individual topics as useful for their own teaching practice. They stated that their existing knowledge and competencies were tested, some information broadened their horizons, and they appreciated that some information was presented in an interesting and useful context. Some of the participants were not able to assess the practical applicability of particular topics in their work and teaching practice.

During the course, participants performed some processing tasks. Teachers used interactive methods in their lessons, while students had opportunities to express actively their opinions, suggestions and experiences of educational practice, and discuss problems from their teaching practice.

4 English language competencies

Academic English can be defined as: "…English of intellectuals, scientists, experts, researchers and other members of academia used for communication and work. It is understood as an elegant, polished and complex language style in which accuracy, objectivity and non-emotional comments are emphasized" (Stepanek, de Haaff et al., 2011).

Academic English can be used for lectures, presentations, seminars, discussions, consultations, practical exercises, individual studies, literature studies, project work, seminar papers, and during study periods or work abroad. It can be stated that the above-mentioned activities require language skills which are mastered by all academic staff in general. Academic English has an especially specific position in vocabulary. Academic language is interdisciplinary and includes general vocabulary, terminology of specialization, and specific terminology of academic English.

Teachers of English have prepared a course to enhance academic staff´ skills in teaching their subjects in English. The first step in the course preparation was to find out:

- if the academic staff are interested in a course of academic English;
- what is their level of English;
- what are their expectations from the course of English.

A questionnaire was sent to all academic staff of the Faculty of military leadership, and 79 sent back their answers and expressed their interest in a course. Based on the questionnaire survey, teachers of English prepared three courses at different levels: pre-intermediate (B1 according to the CEFR), intermediate (B2) and upper-intermediate (C1). All courses ran over two semesters and were divided into two parts: theoretical and practical. The theoretical part was focused on increasing academic skills for teaching technical subjects in English, for example a revision and consolidation of complex grammatical structures used in an academic environment, vocabulary associated with a wide range of academic subjects, a language for presenting information, and data conducive to effective oral and written communication. The second part of the course placed emphasis on presentations and mini-lessons of individual participants. The advantage of the course of English was a combination of full-time teaching and online study supports in LMS Moodle (interactive exercises, presentations, e-tests).

4.1 Questionnaire Outcomes

At the end of the first semester, the authors decided to find out whether the course participants were satisfied with the topics, the quantity and level of study materials, the number and difficulty of e-tests. 72% of participants said that the topics, quantity of study materials, and the number and difficulty of e-tests were adequate. Another objective of this survey was to discover whether, and which, suggestions,

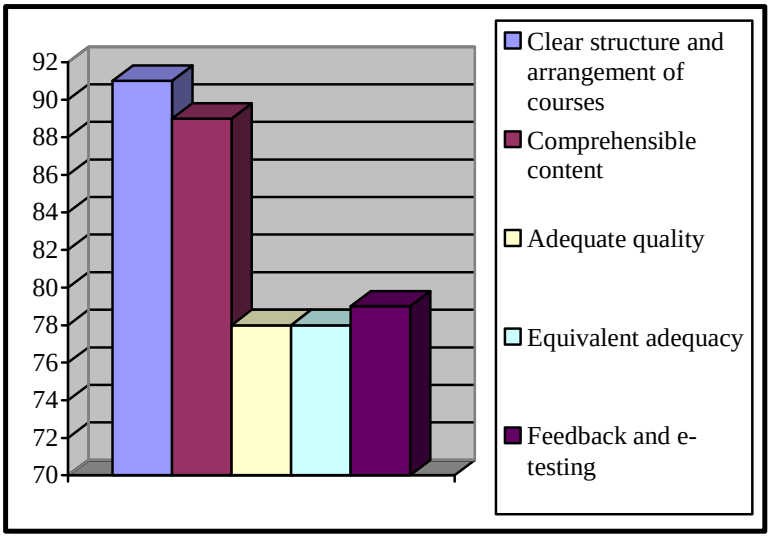
comments, advice and ideas they suggested. Among the most frequent comments were: more examples of discussed topics, more communication, more terminology, and more face-to-face revision during lessons. Among suggestions for the summer semester curriculum the most frequent recommendations were:

- a list of phrases for managing lessons in English; more grammar with detailed explanation, especially phenomena typical for professional English;
- conference English;
- translation: general rules and practice;
- differences between British and American English;
- conversation with a native speaker,
- more grammar and more detailed explanation of typical phenomena of professional English in the courses of lower level proficiency;
- correction of every mistake.

Most of the suggestions were incorporated into teaching in the summer semester, a list of phrases was saved in LMS Moodle, and more lessons with a native speaker were organized. However, some recommendations could not be included, e.g. correction of every mistake, however teachers instead wrote a summary of the most common mistakes made during lessons, presentations and written work.

At the end of the second semester another questionnaire was carried out. Its objective was the course assessment. The course participants highly assessed the course materials in particular, study materials, course content, and a practical element of a course, for example mini-lessons. All participants (100%) positively evaluated the combination of full-time teaching in combination with LMS Moodle. Among the most frequent answers were: clear structure and arrangement of courses; equivalent adequacy, adequate quality, comprehensible content, feedback and e-testing (Graph 1).

Graph 1: Assessment of study supports in LMS MOODLE

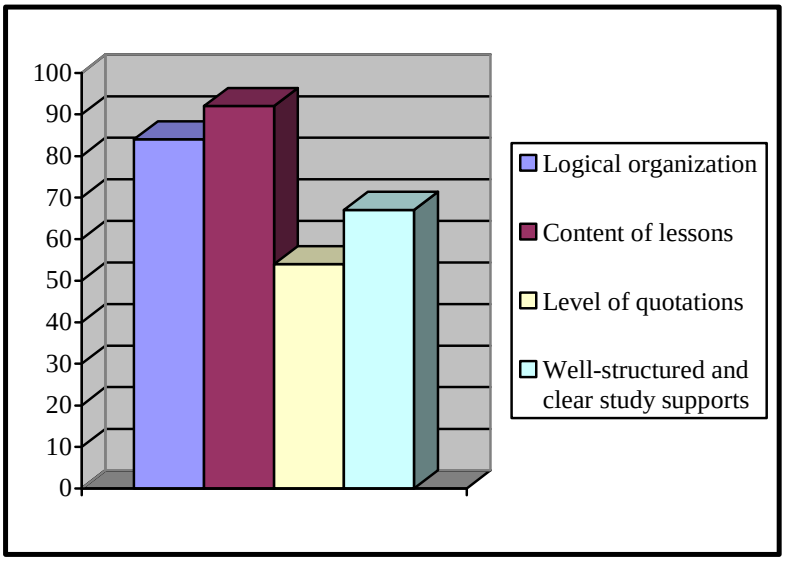


Resource: own

A further element of LMS MOODLE assessment was focused on the study supports. The next graph shows (Graph 2) that the majority of comments by the course participants were positive: logical organization, well-structured and clear study supports. Critical comments were aimed at the level of

quotations, which indicates the importance and sensitivity of this issue. All comments and suggestions were incorporated into the final version of study materials and the Academic English Handbook which will serve as a prerequisite for further independent study.

Graph 2: Study support assessment



Resource: own

It can be stated that the courses of language competencies of academic staff in English fulfil their objective, which was to provide teachers of special subjects with enough study materials and to practise their own teaching activities in English (presentations, mini-lessons)

5 Conclusion

Both courses are good examples of how you can positively influence the pedagogical and psychological competence of university-educated professionals. This approach also contributes to the fact that teachers perceive it as the management interest in their further development and they can feel more intense relationship with their faculty or university. It can have a positive effect on strengthening their stronger identification with the vision, goals and values of the institution in which they work. It can also contribute to forming a positive relation of students to education, to their teachers as personalities as well as to their faculty or university as an institution. Both courses are a good example of blended learning too as they combine face-to-face lessons with learners' independent work. The learners independent work was supported by study supports in LMS Moodle. ICT implementation successfully reflected the changes to the content (in terms of interactive) and software processing courses. Both courses were positively evaluated by the participants as they respond to the current need, emphasize and incorporate the views and recommendations of learners, academics, and thus respond to their current needs.

Analysis of Correlation between Intellectual Capital and Traditional Key Performance Indicators within the Automotive Industry

Andreas Kompalla, Bucharest University of Economic Studies, Romania, andreas.kompalla@gmx.de
Jan Kopia, Bucharest University of Economic Studies, Romania, j.kopia@gmx.net
Gabriela Tigu, Bucharest University of Economic Studies, Romania, gabriela.tigu@ase.ro

Abstract

Enterprises all over the world struggle to define and extend their very specific competitive advantage in order to gain market share and beat their competitors. A company's value and therefore status is often measured via its assets. For traditional branches such as machinery these assets are mostly tangible. But as technological progress and products themselves can be adapted by many companies much quicker than in the past, terms like culture, network and intellectual capital find their way into business strategies.

This research will analyze the correlation between Intellectual capital and the sales growth rate as well as the operating margin within the automotive industry in order to describe the priority and focus for this aspect within business strategies. Within scientific literature Knowledge Management measurement of automotive enterprises has not been in focus so far. This study will provide insights regarding the status of Knowledge Management within the automotive branch via analysis of VAIC values. Furthermore the correlations between various traditional key performance indicators have been analyzed in numerous scientific papers. This research in contrast combines knowledge management related indicators with traditional business performance factors. The analysis provides evidence that the Knowledge Management measure, VAIC, is dominated by the component of Human Capital Employed which is correlating with further researches. Additionally the quantitative results indicate that there is a strong correlation between VAIC and operating margin as well as the sales growth rate, which should emphasize the importance of knowledge (and Knowledge Management) as a crucial asset for (automotive) companies.

Keywords: Intellectual capital, performance, automotive, KPI, measurement

0. Introduction

This research paper is focusing on the correlation of the Value added intellectual capital coefficient and further key performance indicators with respect to the automotive industry. Based on an initial literature review regarding business performance and knowledge management, their correlation will be summed up according to scientific literature and set into the context of organizational learning. Within the quantitative analysis the VAIC value and its components will be calculated for selected companies as well as compared across branches. This is the basis for comparing these values with traditional business key performance indicators such as the sales increase and operating margin. The last chapter is focusing on further research and provides a summary to the content of this paper.

1 Literature review

1.1 Performance and knowledge management

Since the 1980s various concepts of organizations were suggested by scientists. In the resource-based view the competitive advantage was developed through tangible and intangible resources (Mwailu & Mercer, 1983; Wernerfelt, 1984; Rumelt, 1984; Penrose, 1959). In that view resources have to be valuable, rare, in-imitable, and non-substitutable in order to be the key resources necessary for a company to attain a competitive advantage. Terms as (company specific) *capabilities* (Amit & Schoemaker, 1993) became important and were defined as "a special type of resource, specifically an

organizationally embedded non-transferable firm-specific resource whose purpose is to improve the productivity of the other resources possessed by the firm" (Makadik, 2001). Resources must be bundled (Sirmon et al., 2003) to choose the strategy to attain the necessary competitive advantage. In the same context Michael Porter suggested two strategies of competitive advantage - lowering costs and differentiation. Both highly depends on the capabilities and resources of a firm including the skills of its employees. Prahalad et. al. (1990) writes about core competencies which also focussed resources and skills of a firm which needs to be harmonized in order to define the firm in the marketplace. Skills and knowledge are vital components. The core competencies have to fulfil three criteria:

1. Provides potential access to a wide variety of markets.
2. Should make a significant contribution to the perceived customer benefits of the end product.
3. Difficult to imitate by competitors.

In this concept it is suggested to develop ideas for future solutions especially by using intangible resources. Teece et. al. (1997) developed the concept of dynamic capabilities as "[…] firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments." It is not only important to have the right competencies as in the theories above but also to react appropriate in changing environment. There is a constant need for the organization to challenge the current knowledge and develop new ideas and solutions. "The concept of dynamic capabilities, especially in terms of organizational knowledge processes, has become the predominant paradigm for the explanation of competitive advantages. However, major unsolved—or at least insufficiently solved—problems are first their measurement and second their management…" (Cordes-Berszinn et al. 2013).

New Approaches and strategies needs to be developed especially considering the constantly developing effects of globalization, deregulation, and technology. A clear understanding of the business models is necessary to get a better understanding of new developments in that area. Developing new products and services through constant innovation is more important than ever before. "This new environment has also amplified the need to consider not only how to address customer needs more astutely, but also how to capture value from providing new products and services" (Teece, 2010). Teece also states that "a business model is more generic than a business strategy. Coupling strategy and business model analysis is needed to protect competitive advantage resulting from new business model design". In today's market it is important to have a hard-to-imitate, effective, and efficient business model in order to create value. Capturing the value from innovation is the key element of business model design (Teece, 2006). Makadoc (2001) sees one form of engagement capabilities in transferring knowledge within a firm. Organizations have to learn constantly and deal with knowledge and learning becomes vital in the future.

1.2 Knowledge management, organizational learning, and Intellectual Capital

The ability to manage knowledge is becoming increasingly more crucial in today's knowledge economy. The creation and diffusion of knowledge have become ever more important factors in the competitive landscape. More and more knowledge is being regarded as a valuable commodity that is embedded in products (especially high-technology products) and in the tacit knowledge of highly mobile employees (Dalkir, 2005), which is also reflected by the EUROPE 2020 initiative.

Knowledge management (KM) is defined differently depending on the field of science and the perspective. The definition of KM as "…the capability of a company as a whole to create new knowledge, disseminate it throughout the organization, and embody it in products, services and systems" (Nonaka and Takeuchi, 1995) makes clear that KM is an important value. Economists see KM as valuable asset or Intellectual Capital (IC) of a firm (Bontis et al, 2001). The origin of Intellectual Capital was set Karl-Erik in the mid-1980s and later further developed by Edvinsson and Malone (1997), Steward (1997), and Sullivan (1998). Steward (1997) defines it as "intellectual material […] to create wealth by producing a higher valued asset". It therefore needs to be reflected in the numbers in the capital market, for instance by using the difference between the book value and

the market value of an organization, which is the Intellectual Capital (see figure 1). Macro-economic research today is mainly based on definitions of categorization developed by Edvinsson and Malone.

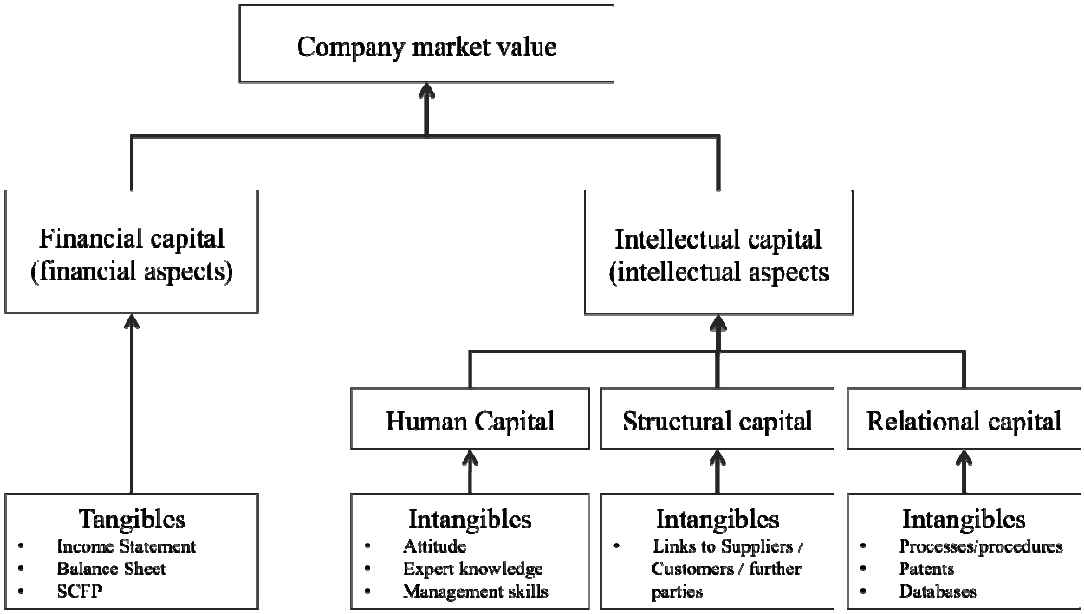

Figure 1: Intellectual Capital framework: its relationship to market value. (Source: Own elaboration based on Johnson, 1999)

Figure 1 visualizes that the market value of a firm is strongly influenced by many aspects of the Intellectual Capital in form of several intangible assets - most of them closely related to skills, knowledge and knowledge management. Papula et al. (2011) suggested to aspects of knowledge management and the evolution of it differentiating the object and aim of knowledge management (see figure 2).

But this value is only rarely used today (one famous example is Skandia, as the first company which reported intellectual property) even though intellectual assets are found in all levels of an organization – from the operational, over tactical to strategic level. There is also no common scientific understanding of how Intellectual Capital influences organizations and how to measure that.

Intellectual Capital is also known as knowledge capital, something which is also used by economists which also talk about the information and knowledge era, the hidden value, and the human capital. Sustainable competitive advantage as defined before is now tied to individual workers' and organizational knowledge (Bontis, 2001). Scientists as Bontis (1998), Wang und Change (2005) etc. have proven that there is a positive connection between Intellectual Capital and performance. The performance of a company is highly depended on the knowledge of the employees and on the collective or organizational knowledge (Sudarsanan et al., 2003). Dalkir (2005) defines KM as "the deliberate and systematic coordination of an organization's people, technology, processes, and organizational structure in order to add value through reuse and innovation. This coordination is achieved through creating, sharing, and applying knowledge as well as through feeding the valuable lessons learned and best practices into corporate memory in order to foster continued organizational learning. This is why organizational learning becomes an important topic even though the topic itself is already been studies since the 1970er.

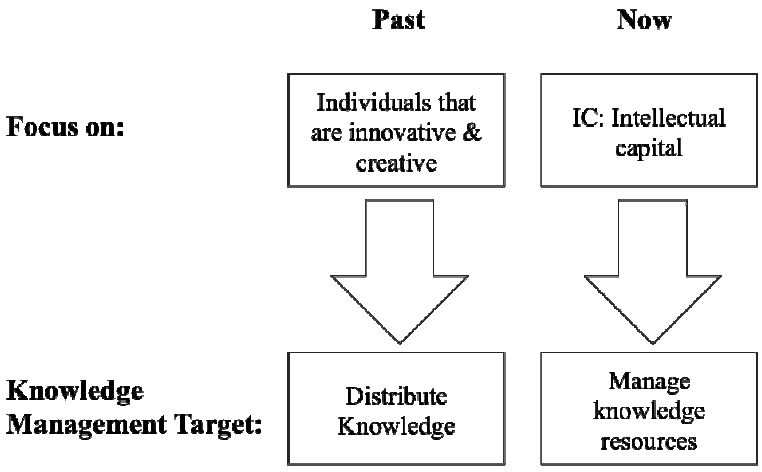

Figure 2: Evolution of knowledge management related to its object and aim (Source: Own elaboration based on Papula et al, 2011)

Organizational learning was popularized 1990 by Senge and used by other scientist as Crossan et. al (1998) with the following definition: "Organizational learning is the process of change in individual and shared thought and action, which is affected by and embedded in the institutions of the organization".

Saving, using and exchanging knowledge seems to be important factors within organizations. Learning and the learning process is another important aspect which is studied by scientists (e.g. Crossan et al., 1999, Argyris et al., 1976, 1996) including fundamental approaches such as "single loop learning", "double loop learning", and "triple loop learning" as well as aspects from different scientific areas. In order to be innovative, companies need to use and manage learning strategies (Hatchuel et al., 2005). Even though there is no clear consensus about the effect of training regarding job performance (A famous sentence was made by Georgesons (1982),' "I would estimate that only 10 percent of content which is presented in the classroom is reflected in behavioral change on the job"), the positive effects on human resource development in general was shown by different authors as well (Huselid, 1995, Jackson & Schuler, 1995, Zacharatos et al. 2005 etc.). All of them found empirical evidence of the benefits of high performance work systems (including management system standards as Total Quality Management etc.), HR-strategies, leadership on the performance of firms.

1.3 Correlation of Business performance and intellectual capital

Organizational Learning, Knowledge Management, and Intellectual Capital have similar aspectsAccording to Vera et. al. (2001) the "OL field has been the most explicit one in explaining the cognition and behavioural aspects of the learning phenomenon, the KM and IC fields do not only focus on cognition, but also on the action-orientation and utilization of the knowledge acquired and the IC accumulated". The authors argue that learning within an organization is the process in which knowledge and therefore Intellectual Capital is created.

But this knowledge also impacts the future learning. There are scientific authors who provided evidence that learning leads to better performance (Nahapiet & Ghoshal, 1998) but also that there is no clear link between it (for instance Huber, 1991). Research has shown that it is a critical capability for firms to apply organizational learning in order to generate ideas and in order to be innovative (Madhavan et al., 1998; Lynn at al, 1998). Vera et al. (2001) suggested that all the elements of human capital, structural capital, and relationship capital are grounded on different types of knowledge and therefore be linked together. The same is true for the learning and knowledge management process. When learning, the accumulation of knowledge and intellectual capital is aligned with the firm's strategy, then better performance is achieved. The result is the model presented in *figure 4*

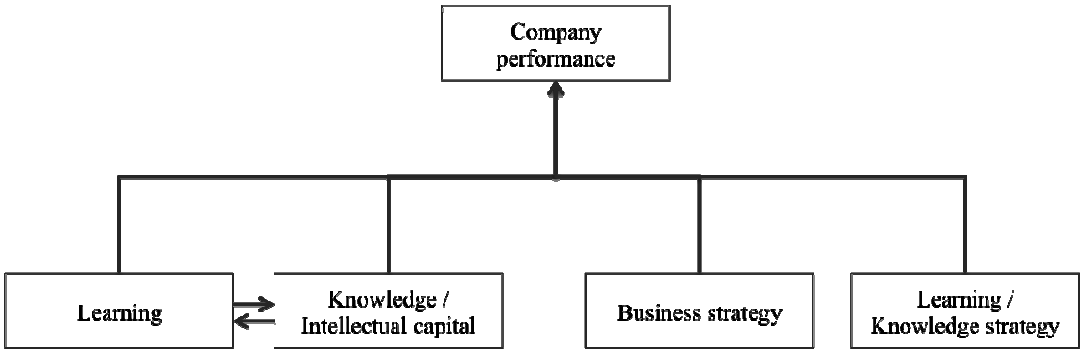

Figure 4: Integrative model of learning, knowledge, Intellectual Capital, and performance Source: Own elaboration based on Vera, 2001)

Scientists have been studying IC and each component of it (Structural Capital, Human Capital, and Relation Capital) for years already. Most studies conclude that IC has influence on the performance of firms (Bontis et al.(2000), Bollen et al. (2005), Cohen and Kaimenakis (2007), Mavridis (2004), Chan (2006), Appuhami (2007), Ting & Lean (2009), Al-Twaijry (2009), Kamel (2012)). Nevertheless this area of research is still scarce. Most of the studies are of qualitative nature. There is still a disagreement of the right method to measure IC and its impact on firms' performance.

1.4 Measurement of Knowledge and Intellectual Capital

As said earlier, measuring of Intellectual Capital or knowledge is a complex topic. Different KM-models have been developed over the years to get a better understanding of knowledge itself and knowledge transfer within a company. Also metrics have been developed to assess the knowledge management process for a better knowledge management strategy. The three most cited metrics in that area is benchmarking (Tiwana 2000), balanced scorecard, and the house of quality (Quality Function Deployment or QFD). New frameworks were developed with many similarities of these metrics including the European Framework of Quality Management (EFQM), Knowledge Scorecards, Intellectual Capital management, Economic Value Added (EVA) etc. The classic balanced scorecard (Kaplan and Norton 1992/1996) measures performance in four perspectives: financial, customers, internal processes, and learning and growth. This balanced view on financial and non-financial data represents the performance of the business. A newer adoption of balanced scorecards are Knowledge Scorecards with focusses knowledge organizations in particular (Deking 2002; Kaps 2001; Fairchild 2002). The balanced scorecard dimension learning and growth mainly involves the capabilities of employees, their skills, motivation, and awareness as well as the information system capabilities which represent the above mentioned topics. Other methods to measure more than just financial values were suggested by scientists for a longer time, including Publics (2000) Value Added Intellectual Coefficient (VAIC), Stewards (1997) Calculated Intangible Value (CIV), Levs (2001) Intangible Driven Earning (IDE), Skandias "Skandia Navigator", and IC Rating which included aspects of the Intangible Asset Monitor (Sveiby, 1996). According to Sveiby (2014) all measurement methods can be divided into the four groups: Direct Intellectual Capital Methods (DICM), Market Capitalization Methods (MCM), Return on Assets Methods (ROA), Scorecard Methods (SC).

Measuring Knowledge and IC is a difficult task and the suggested measurement methodologies and tools have not yet found a wide agreement, neither in scientific research nor in practise. In this paper the authors use the VAIC-calculation which part of Sveibys third group of measurement (ROA).

1.5 Importance and calculation of VAIC

This paper focuses on the VAIC (Value Added Intellectual Capital Coefficient) method developed by Pulic (2000, 2003 and 2005). VAIC measures the effectiveness of key resources in the enterprise by calculating the Value-added and the three types of intellectual capital: human capital, structural capital, and capital employed (see *figure 5*).

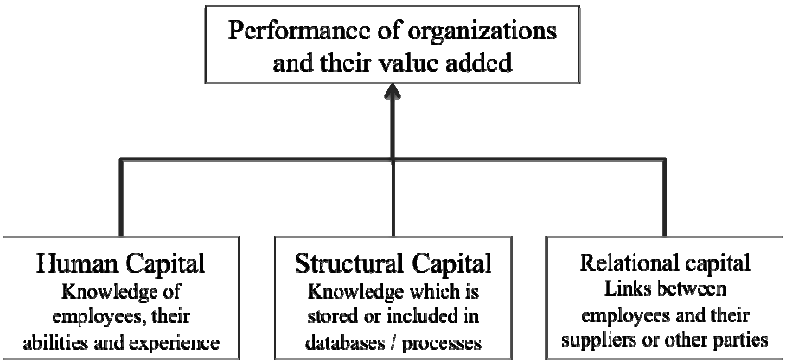

Figure3 : Link between IC and organizational performance (Source: Own elaboration basSumedrea, 2012)

The benefit of VAIC against other methods, which are often criticized of their underlying subjective indicators is that it is solely based on company's balanced figures which make it easy to calculate the value and to compare different organizations with each other. VAIC allows for a standardized and consistent basis of measurement, making it possible to conduct an international comparative analysis more effectively when using a large sample size and spanning across various industrial sectors. Third, VAIC is a straightforward equation, that meaning various internal and external stakeholders can easily calculate it. VAIC can be seen as innovative indicator of Intellectual Capital efficiency (Lazzolino and Laise, 2013). Similar conclusions are drawn by other scientists which researched on the relationship between IC and performance (Firer and Williams (2003), Chen et al. (2005), Ting and Lean (2009), Malloul (2010), Clarke et al. (2011), Guo et al. (2012)).

In this study the VAIC is calculated as follows

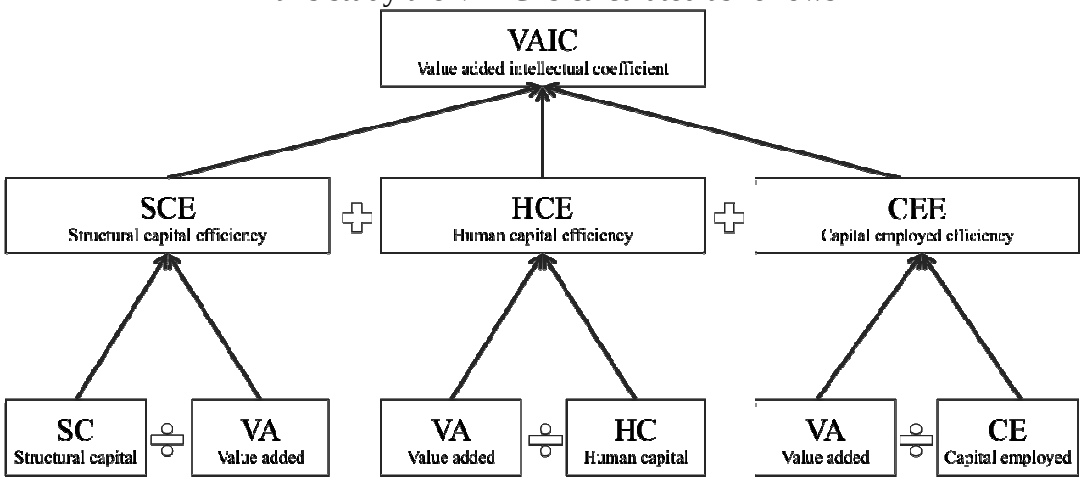

Figure 6: VAIC calculation (Source: Own elabo. based on Stahle, 2011)

VAIC = CEE + HCE+ SCE (1) (or: ICE + CEE)

CEE represents capital employed efficiency:

CEE = VA/CE (2)

HCE represents human capital efficiency:

HCE = VA/HC (3)

SCE represents structural capital efficiency:

SCE = SC/VA (4)

CE = Capital employed

HC = Total investment on employees (Human Capital)

SC = VA – HC (or: Total assets – Total current liabilities)

VA: Value add is seen as the sum of benefits obtained by all the stakeholders: net income + salaries and wages + interest (tax) + dividends + depreciation and amortization

2 Quantitative analysis

2.1 Method and database

The database for the analysis has been derived from relevant annual and financial reports of 6 globally operating automotive enterprises for the respective years of their business strategies ranging from 2008 to 2014 as well as from publications of their respective business targets. Via linear regression models and descriptive analytics the VAIC value itself and the correlation to other key performance indicators will be analyzed in chapter 2.3.

2.2 Hypotheses

The purpose of this study is to analyze the correlation between the Intellectual capital of a company and its financial performance in the automotive industry using the VAIC method. The calculated VAIC values will be analyzed regarding its components, compared with other branches and evaluated according to the correlation to operating margin as well as the annual sales growth rate. The following hypotheses will be evaluated:

1. VAIC values within the automotive industry are dominated by the component of Human Capital efficiency.
2. Average VAIC values within the automotive industry can be compared with other branches such as the banking sector. The average of automotive VAIC values is lower than in non-machinery based industries.
3. The operating margin and the VAIC-value do show a high degree of correlation.
4. The sales growth rate and the VAIC-value do show a high degree of correlation.

2.3 Quantitative Analysis of VAIC value components, comparison between branches and correlations to KPIs

Since scientific literature regarding the VAIC values for global automotive manufacturers is not extensive this chapter will compare the average VAIC value with other branches such as banking sector and regions (e.g. Poland and Romania). The research data is generated based on global automotive groups and single automotive OEMs with headquarters in Europe and Japan.

2.3.1 VAIC components

As described in chapter 1.5 the VAIC value is generate via the sum of HCE, SCE and CEE. *Figure 7*

describes the aggregation of each component to the final VAIC value based on the average of each company within the research database. The proportion of the VAIC value is defined by approximately 66 % of HCE, 18 % of SCE and 16% of CEE, which is in the same range as described by *Svanadze and Kowalewska (Svanadze et al., 2015)* regarding the WIG 20 companies in Poland. This means that, based on the available data, VAIC components within the automotive branch seem not to differ significantly from other branches.

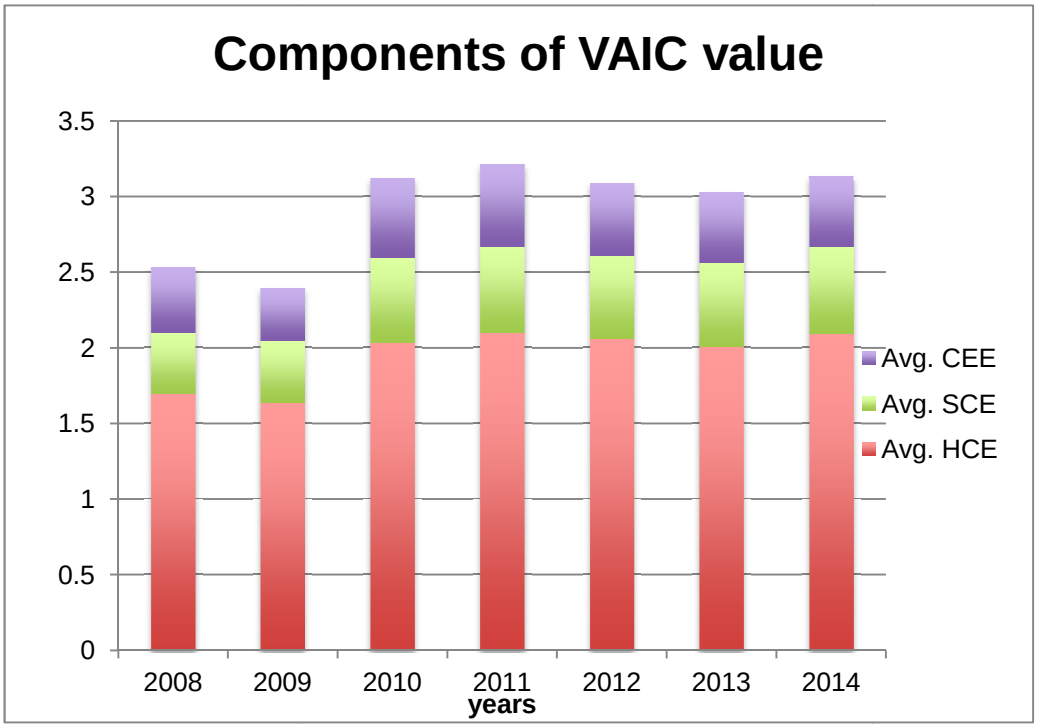

Figure 7: Components of VAIC value within research database according to financial year (Source: own elaboration)

The range of VAIC values is varying based on the financial year and the respective company. *Table 1* shows the values as well as the average per brand from 2008 to 2014. Except Nissan and Daimler the VAIC values vary in a range of 15 to 25 % within the defined timespan. Due to the financial crisis in 2008 and 2009 the lowest VIAC values have been derived for these two years.

Table 1: Average VAIC value within research database according to financial year (Source: Own elaboration)

VAIC values						
Year	**Volkswagen group**	**Skoda Group**	**Daimler Group**	**Audi Group**	**BMW AG**	**Nissan**
2008	2,96	3,73	2,32	3,33	3,74	0,74
2009	2,32	3,05	1,73	2,85	3,97	2,65
2010	2,72	3,70	2,96	3,37	4,55	3,45
2011	2,68	3,83	3,07	3,56	4,79	3,42
2012	2,50	3,62	2,93	3,53	4,60	3,41
2013	2,57	3,50	3,09	3,28	4,26	3,45
2014	2,63	4,08	3,12	3,24	4,21	3,62

Average per brand	2,63	3,64	2,75	3,31	4,30	2,96
Total average	**3,27**					

2.3.2 VAIC value comparison between branches

Table 2 shows that the average VAIC value within the research sample is 3,27. This value is higher than the average value calculated by *Nedelcu et. al. (2014)* regarding Romanian automotive enterprises. In contrast, compared to other branches such as banking sector or the WIG 20 companies this value is significantly lower. As these values are based on different timeframes it is not possible to directly compare them with each other. But the VAIC value differences are indicating that branches, which are focusing on there employed capital, such as the banking sector, do also have a higher VAIC value. The increase of the VAIC value within the Automotive branch could indicate that also in this branch knowledge management and the value of intellectual capital is increasing.

Table 2: Comparison of VAIC values between different branches and regions (Source: Own elabo-ration and C.f. Abdulsalam et. Al. (2011), Svanadze et. Al. (2015), Nedelcu et. Al. (2014))

Branch	Average VAIC value
Automotive branch (paper research database 2008 - 2014)	3,32
Banking sector Kuwait (1997 - 2006)	5,12
„WIG 20“ Poland (2010-2013)	4,27
Automotive branch Romania (2000-2013)	1,34

Based on the research database of 6 automotive OEMs and their annual reports there is no consistent central KPI, which is used for reporting. E.g. while BMW is focusing on Return on capital employed (ROCE as central KPI defined in annual report 2007), Daimler is concentrating on value added and Nissan is targeting the operating margin and market share (according to annual reports of BMW, Daimler and Nissan). The database has therefore been extended to the respective KPIs, which are commonly used: Sales growth rate and operating margin. The correlation will be analyzed in the following chapter.

2.3.3 Analysis of correlation between VAIC and KPIs

This chapter focuses on the correlation of knowledge management measurement KPIs which is the VAIC value, with other business performance indicators such as sales growth rate, operating profit, EBITDA, return on investment or return on capital employed.

Correlation between VAIC and Operating margin:

The coefficient of determination (R^2) shows the proportion in which the independent variable explains the dependent variable's variation. It will be used in order analyze the correlation of VAIC and the operating margin.

Table 3: Correlation of VAIC and operating margin

Correlation of VAIC and Operating margin	
Average R^2	55,57 %
Average R	74,55 %

Within the research sample the VAIC value explains 55,57 % of the operating margin's variance, which indicates a strong correlation of these two values (*see table 3*).

Within the research sample, the correlation of VAIC values to operating margin is varying. The highest correlation can be seen by the example of Nissan with R^2 of 0,96 (*see figure 8).*

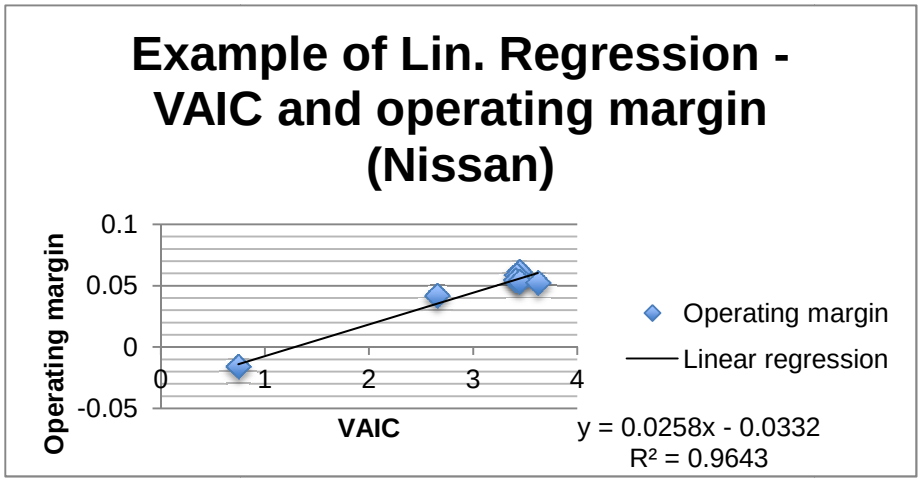

Figure 8: Correlation of VAIC and operating margin – example of Nissan (Source: Own evaluation based on annual reports)

Analysis of correlation between VAIC and sales growth rate:

Compared to the analysis of Romanian automotive enterprises by Nedelcu et. al. (2014) there is a significant difference of correlations between the VAIC value and Sales growth rate. While in the study of Nedelcu 12,71 % of the dependent variable is explained by VAIC, the research database of six global operating automotive enterprises shows a R^2 value of more than 50 % (see table 4).

Table 4: Correlation of VAIC and sales growth rate

Correlation of VAIC and sales growth rate	
Average R^2	**53,29%**
Average R	**73,00%**

Similar to the correlation of VAIC and operating margin, also the correlation of VAIC and sales growth rate is depending on the research sample. The highest correlation has been identified via the example of Daimler with R^2 of 0,92 (see figure 9*).*

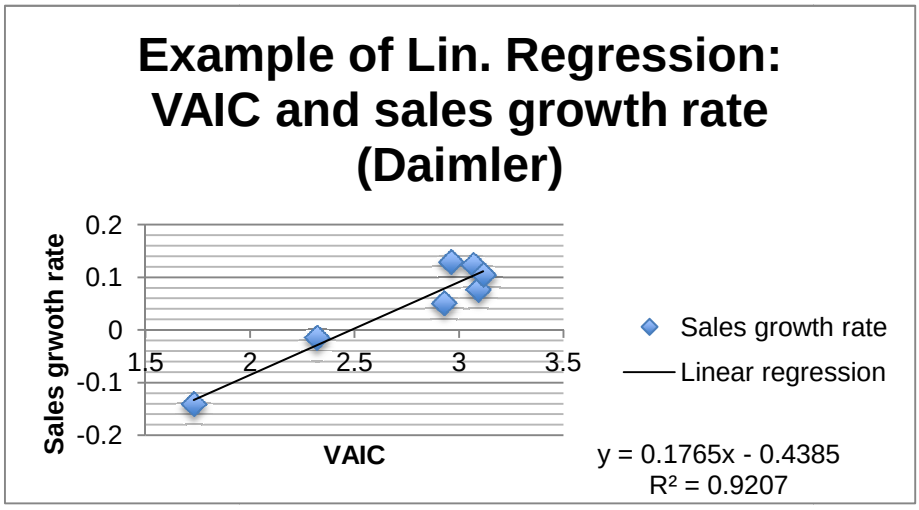

Figure 9: Correlation of VAIC and sales grwoth rate – example of Daimler (Source: Own evaluation based on annual reports)

3 Appraisals and Conclusion

The conclusions and outcomes of this study are based on the analysis of annual reports within the automotive industry. Although the VAIC value can be calculated on the information published in these reports, the interpretation of the input data can vary. It is crucial to separate between group, single enterprise or even division values such as sales or profit. Additionally, the research results would be more accurate if the database could be extended to more than 6 automotive enterprises also focusing on US car manufacturers such as General Motors or Ford. Due to missing input values, these companies have been excluded so far. Considering these facts following conclusions can be derived:

The VAIC value is dominated by the component of HCE (with roughly 66 % within the research database). Furthermore VAIC values are in general higher within branches, which are less dependent on machinery and tangible assets compared to traditional industry such as the automotive branch. However, the average VAIC values have been increasing from 2008 to 2014 by approx. 25 %, which shows that also these branches are transforming towards the megatrends of digitalization and service orientation. Based on the linear regression models, in general there is a high statistical correlation of the VAIC value and respective key performance indicators. Additionally the third hypothesis has been proven truth, as the VAIC value and the operating margin are correlating within the research database to a high degree. And also the second business performance indicator, the sales growth rate, is correlating to the VAIC value within the automotive industry.

In conclusion the research paper shows the importance of Pulic's VAIC value for knowledge management measurement and it's correlation to further business performance indicators within the automotive industry (indicating that the hypotheses stated in chapter 2 have been proven truth).

Future research on this topic will concentrate on multi-regression models in order to analyze the contribution of the VAIC components to each of the business key performance indicators and to analyze if there are further factors affecting traditional KPIs. Additionally the research database will be extended to a wider timeframe as well as multiple enterprises and more branches need to be analyzed in order to find similarities and differences regarding the VAIC values.

Acknowledgement

I want to thank Prof. Olaru and Prof. Tigu for providing the opportunity to do research in this field and for supporting the analysis with creative input. Additionally I am grateful that my girlfriend is granting me enough time to perform this scientific analysis.

Measuring innovation capabilities - the fourth generation indices

Hana Scholleova, Czech Technical University in Prague, The Masaryk Institute of Advanced Studies, Department of Economic Studies, Kolejní 2a, Prague 6, 160 00, Czech Republic, hana.scholleova@cvut.cz

Abstract

This article aims to show the issue of benchmarks for innovation and restrictions on use. There are many metrics available to use for measuring innovation. Some of the metrics are well-known and globally widespread (Innovation Union Scoreboard, 2015). Eurostat manages and unifies the methodology for measuring the intensity of innovations in enterprises in many regions, including the Czech Republic. This ensures consistency and commensurability methodology. The aforementioned rankings are objective for comparing the intensity of innovation among themselves, their inputs are complex and hard data from the past. However, these indices provide businesses with virtually no information about what they should do differently, or where the limitations are in terms of innovative potential. Metrics based on data of soft nature- subjective inputs are developed for this purpose. Their outcomes are not completely commensurable, but give companies enough feedback. This article analyzes the SAII index thus created in the Czech Republic.

Keywords: innovation, innovation metric, soft indicator

Introduction

There is a direct interest in supporting innovation, which leads to the need to assess the status and progress in this area and subsequently to the creation of measurement tools at all levels. The most widely used measure at transnational level is the Summary Innovation Index, further SII (Innovation Union Scoreboard, 2015), which is regularly evaluated and published. SII processing is fast and precise and is based on multi-criteria evaluation clearly defined and well measurable indicators. SII allows individual states to determine not only the current situation but also position in comparison with other countries and the shift of individual criteria with respect to the previous period. On a similar basis, the Global Innovation Index is created, further GII (The Global Innovation Index, 2014). The advantage of the GII is that in comparison enters 143 countries around the world, not just Europe and the developed regions. At the national level, innovative corporate behavior is tracked mainly by regular statistical survey. This statistical surveys are ordered by national statistical organizations in developed countries and within Europe there is the effort to unify the indicators monitored and evaluation methodology (Czech Statistical Organization, 2016). Results include: the detection of innovation barriers, the shift in the innovation behavior of companies and the ability to adjust the system of state support for the most effective impact. From the foregoing it is clear that the scale should be used not only passively but actively. Scales should be used to further decisions about the future path. The question is how to measure innovative behavior at the company level, so that the management has brought a similar decision support.

When looking at the global and national scale, it is possible to see the fundamental trend: the shift from objectivity to the necessary information capability with a focus on further decisions. Global scales include mainly indicators that are general assumptions or outcomes of innovative behavior, are current and well and objectively measurable. Measurements conducted by statistical authorities at the national level already measure how hard indicators (% of sales from innovative products etc.), but also soft indicators, which sometimes may be distorted by personality *(What is the biggest obstacle to innovation? Who is the most important element of co-innovation process?).*

The question is: What is the aim of monitoring the behavior of innovation for the company? For the company as an entity, it is not essential to objectively compare all the companies in the world, but to fulfill its objectives. These are mainly increases in value which nowadays must be based on the

creation and competitiveness that is directly influenced by the behavior of innovation within the company. For its evaluation, it is possible to use both hard and soft scales.

Innovation Measurement

Research BCG show (Andrew et al, 2009), that only 32 percent of executives are satisfied with their company's innovation-measurement practices. And that percentage has been falling. While most executives—73 percent of respondents—believe that innovation should be tracked as rigorously as other business operations, only 46 percent said that their company actually does so. The majority of companies continue to rely on a handful of metrics to measure the full scope of their innovation activities. Fifty-two percent of respondents said their company uses five or fewer metrics. But that number is starting to rise. A surprisingly small number of companies—27 percent of respondents—attempt to drive innovation by linking employee incentives to innovation metrics. But that number, too, is edging up. The most widely tracked components of innovation are overall company profitability (79 percent of respondents said their company measures it), overall customer satisfaction (75 percent), and incremental revenue from innovation (73 percent). Companies consider themselves most effective at measuring innovation outputs (such as revenue growth, shareholder returns, and brand impact). They consider themselves far less successful at tracking innovation inputs (for example, dedicated resources, such as people and funds invested) and the quality of their innovation processes.

The big problem is how to measure innovation in the company. There are hard metrics - for example, revenues from innovative products, the payback period for investment in innovation, etc. Metrics recommended (Bartoš, Žižlavský, 2013) are in Table 1. The other columns are added assessment with regard to the potential for the future.

Table 1: Hard metrics, Source: own processing by Bartoš, Žižlavský (2013)

Metric	Exactly measurable?	Impact on future?
Return on investment in innovation	yes	little
The volume of sales from innovative products	yes	middle
The share of revenues from innovative products to total revenues	yes	little
Percentage sales growth due to innovation	yes	middle
Lifetime of Innovation	Not exactly	little
The number of patents per employee and year	yes	middle
Profitability of product innovation	Not exactly	middle
The decrease in cost due to innovation	Not exactly	middle
Sales of innovations per employee	Not exactly	middle
The added value of successful patents	Not exactly	middle

Table 1 shows that most indicators are well measurable, but assess mainly the past. Those that relate to the future, at least partially, are harder to measure.

Most businesses measure results using financial indicators. Managers feel that they should be able to monitor innovative projects using mainly non-financial indicators. These indicators are more forward looking and also provide a better assessment of the progress in real time and the probability of success (Ryan, 2006).

Performance measurement is one of the most critical elements of successful innovation. When measurement systems are not aligned with strategy and adapted to the typical portfolio of business innovation, managers lose a key source of information. This is in turn reflected by lower performance and a decline in financial benchmarks.

The well-known adage says that only what is measured, is also governed. That is why even in the metric system innovation potential scale must be constructed carefully.

Moving away from measurements of hard data from the past does not mean that the results are not measurable.

Only systems are created that:

1) are seemingly biased, because they work with the scoring of activities that can´t be accurately converted into units (currency, etc.)
2) create a summary indices based on a comprehensive view of a company´s activity in terms of inputs, outputs and set procedures.

(Milbergs and Vonortas, 2004) describe four generations of innovation metrics:

1) Output Indicators first generation (1950-1970)
   - Expenditure on R&D, Scientific and technical staff, Capital, Intensity of technology
2) Output indicators second generation (1970-1990)
   - Patents, Publications, Products, Changes in quality
3) Innovation Indicators Third Generation (1990-2000)
   - Innovation surveys, Indexing, Benchmarking of innovation capability
4) Process indicators fourth generation (since 2000)
   - Knowledge, Intangible indicators, Network, Demands, Clusters, Management techniques, Risk/return

One such index (generation 3-4) is compiled by Vacek (2010) and focuses on six groups of soft factors:

1) Strategy and Planning
2) Marketing
3) Product, Technology
4) Quality, environment
5) Logistics
6) Organization and Human Resources

In each of these areas 6 questions were posed- together thus evaluated 36 aspects, and finally on a scale from 1 to 4. The evaluation did not add the results up, every area of the data was evaluated separately. There were also collected selected financial data for the last 6 years and it has been evaluated, too. The disadvantage of such evaluation is compiled, it serves only to a single firm for a possible shift in time when it may create a motivational factor.

A little later is compiled the so-called Self-Assessment Innovation Index - SAII (Špaček, 2015), which evaluates not only the groups but evaluates the company as a whole, ie. the percentage of sets in which the company uses its possible innovative potential. SAII methodology consists of 40 questions, classified into four thematic groups (conceptual activities, management infrastructure, resources, operational management of the innovation process), while the maximum number of points that can be obtained from one of the questions is five. It means, maximum number of points to be gained by answering all 40 questions is 200. The distribution in the abovementioned groups is not the same for all groups (see Tab. 2) In the context of self-evaluation, an expert corporate team will choose from each question the answer that is closest to the business reality.

Table 2: Comparison SAII with Index from Vacek, Source: own processing by Špaček (2015) and Vacek (2010)

Section	Question	Impact on the SAII	Index - Vacek	Question	Impact
Conceptual activities	5	12,5%	Strategy and Planning	6	16,7 %
Resources	7	17,5%	Marketing	6	16,7 %
Management infrastructure	9	22,5%	Product, Technology	6	16,7 %
Operational management of the innovation process	13	32,5%	Quality, environment	6	16,7 %
Financial indicators	4	10,0%	Logistics	6	16,7 %
Non-financial indicators	2	5,0%	Organization and human resources	6	16,7 %
Total	**40**	**100 %**		**36**	

Compared with the index from Vacek, the SAII shows the following main differences:

1) SAll has a resource section
2) SAll has earmarked extra financial indicators
3) SAll has questions more focused on process than on state
4) SAll has a different scoring system: scale 0-2-3-5 and 1-2-3-4 points compared to the scale.

The value of SAII:

SAII= obtained point/ the maximum possible points (1)

where the maximum is 200.

Each company is classified into one of the categories listed below according to the achieved scores (see tab. 3). Companies can also monitor their success in the sub-sections or individual key issues.

Table 3: Valuation Assessment based on value SAll, Source: modification by Špaček (2015)

SAII	Rating	Position
80 – 100%	A	An excellently innovative company
60 - 79	B	A well innovative company
40 - 59	C	An above-average innovative company
20 -39	D	A below-average innovative company
<20	E	Non- innovative company

The greatest benefit of the proposed methodology Self-Assessment Innovation Index (SAII) is based on the breadth and complexity of the applied indicators, and typically also on the ability to analyze and evaluate benefits of both break through and incremental innovations. Unlike existing methods, which focus on comparing countries or sectors (European Innovation Scoreboard, 2015), the SAII methodology focuses on evaluating of the innovation potential of individual companies. The SAII methodology does not serve for an external disqualifying evaluation, but it is a tool of self-reflection for companies and also their clue of how to evaluate their own performance using an innovative combination of hard (especially financial) and soft (behavioral) metrics.

Research and results - a pilot survey index SAII

In practice, the evaluation is conducted via software interfaces, which ensure an adequate user comfort. All calculations are run automatically. In January 2015, a pilot survey was held by a

software solution, which was attended by 45 companies, only 19 companies have submitted complete data. Respondents were allowed to anonymity, but we know that it was Czech business executives who manage medium-sized businesses, technical production, and they make innovations. In Fig. 1 we can see the distribution of the results evaluated companies.

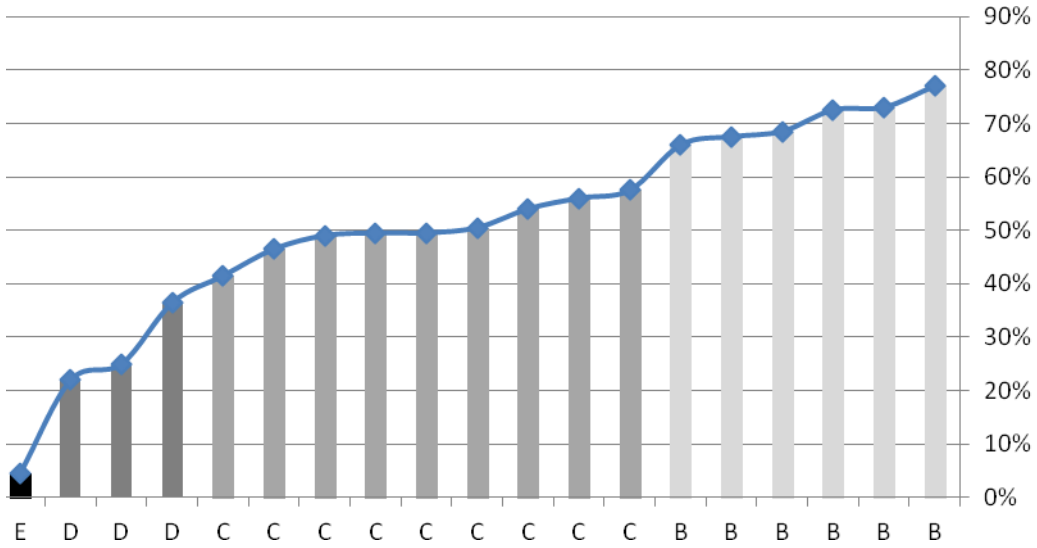

Fig 1. SAII of evaluated companies, Source: own processing

We are very interested in what space the company moved in outcomes between groups. In each section was chosen minimum and maximum result as a group. Opportunities for improvement for the company are illustrated in the so-called. River diagram in fig. 2.

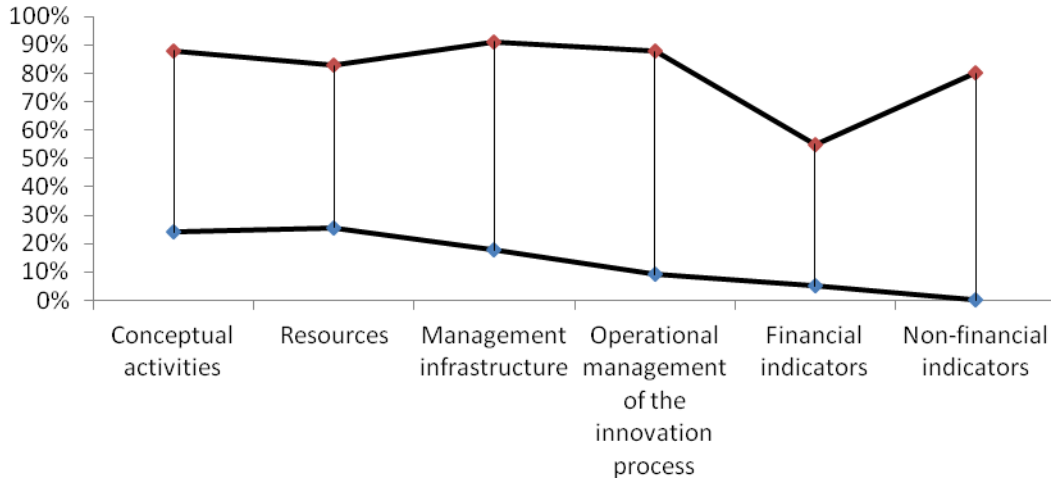

Fig 2. River diagram - real opportunities to improvement, Source: own processing

We can see that the most realistic opportunities for improvement have the most of companies in the field of management infrastructure, operational management and non-financial indicators.

The so-called staircase diagram in fig. 3 shows the status of companies in various areas and their potential for increased activity.

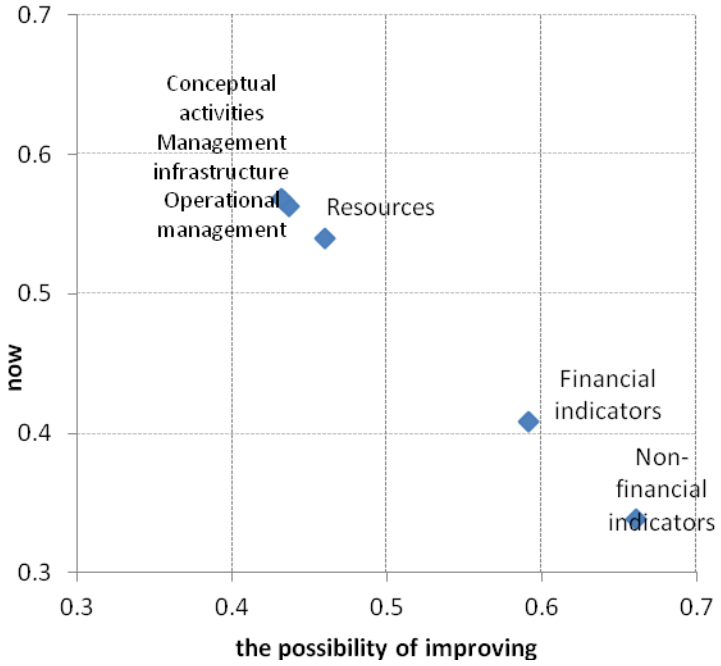

Fig 3. Staircase diagram - groups and its possibility to improve, Source: own processing

Furthermore, we analyzed how together results in the individual groups of questions related. The correlation coefficient was calculated for each group of indicators. Interlinks can be seen in Table 4. The greatest correlation coefficient of 0.89 between infrastructure management and operational management - which is logical and correct when management infrastructure and operational management are linked to one another.

Interesting is the low correlation of financial indicators with other groups. Here it confirms the view that the financial indicators are important for the evaluation of past and motivation, but not as a potential. In other words - they are one of many potentials of innovative behavior of companies in the future, but not an essential one.

Table 4: Correlation between groups of questions, Source: own processing

	Resources	Management infrastructure	Operational management of the innovation process	Financial indicators	Non-financial indicators
Conceptual activities	75%	70%	60%	1%	27%
Resources		76%	73%	28%	39%
Management infrastructure			89%	33%	52%
Operational management				14%	49%
Financial indicators					66%

SAII novelty lies on the idea that they are trying to capture:

- Comprehensive orientation of the company,
- Assumptions of complex construction, development and management of innovation potential,
- There is no comparison with other market players,
- For self-assessment of companies and the finding of reserves,
- Its focus on the future and assumptions,
- Qualitative characteristics that are converted by scaling quantitative.

Conclusion

Managerial practice shows how important is the measurement of innovation for organic development of the organization. Establishment of clear, understandable and transparent methodology is a pre-condition for effective measurement of innovation process effectiveness. The SAII methodology offers a comprehensive evaluation index of the degree of innovativeness of the tested businesses. Self-Assessment Innovation Index (SAII) expresses the innovative potential of a business with the objectivity, including with regard to its ability to reflect modern innovative trends.

It can be stated that it is a measure of the fourth generation.

Informal Networks. Implications for Management of Business Organizations

Simona Buta, Ph.D., „Ştefan cel Mare" University of Suceava, Suceava, Romania,
simonab@seap.usv.ro

Abstract

The organizational structure of a company (comprising all networks / relationships, formal rules and regulations, and those informal ones) may be a contributing factor for the positive and innovative climate within it. This topic has become of great interest in the theory of business administration, especially over the past two decades, as the KM (Knowledge Management) was imposed to the attention of decision-makers in companies; obviously, to lead effectively certain "knowledge networks" requires a more complete vision of the informal relations / networks that occur in the life of a business organization.

Therefore, this paper aims to investigate the impact of informal networks on organizations; this is because he is strongly mediated by the relationship between its interest and the common goal shared by the network members. If they are consistent, informal networks have a positive impact on organizations.

Consequently, we conclude that the strategic directions covered / proposed by top management, together with its formal and informal structure is considered over time in a kind of framework or "matrix" that can facilitate more or less the performance of companies.

Keywords: networks, informal relations, knowledge networks

I. Introduction

In each organization and therefore, each of its components (service, office) employees form - consciously or not - informal groups and networks with similar customs, duties / tasks, rituals; these relationships can evolve beneficially over time from an "informational" type to a "special" type, as confidence and / or the mutual benefits between the members of such a structure strengthen.

Thus, on the one hand we deduce that top management can encourage more or less the consolidation of informal relations between employees and / or between departments; it can motivate a team / group and less motivate a person. Depending on the nature of a company, used technologies, the type of processed knowledge and other similar factors the superior management may use a participatory management or a predominant autocratic one; so, the type of leadership applied at the top of the organizational chart will help in some way to the climate that is established between employees and their native tendency to associate in informal networks.

On the other hand, it must be said that the hypothesis of "blocking" or restricting employees from a company to build and strengthen informal relations / networks is not an acceptable situation in the modern management; this is because the top management that aims such a course of action will inevitably come into contradiction with certain regulations / social norms on human rights, freedom of opinion, freedom of expression etc.. So, the following question arises: "What is the right direction of action of leadership to build informal networks of employees that will favor the exploitation of knowledge and annual performance?"

It is difficult to give a succinct and sufficiently argued answer for the previous question, since the concrete situation of a company, the type of organizational culture, the period of business and the vision of top management are just some of the conditions imposed on the strategies or directions of action leadership may take.

From a theoretical perspective, for a manager to become a real and efficient leader in leading a certain "sequence" of the organizational chart he needs vision, realism, ethics and courage in formulating challenging tasks for the subordinates and then suggesting ways to meet those tasks.

II. Sources of formation of informal networks of business organizations

Informal networks form and evolve naturally beyond the interests of the organization (they may coincide, however, with these interests, in which case we call them positive informal networks or can contravene with to the overall goal of the organization, in which case we call them negative informal networks); the individuals create such networks due to common interests and concerns, social needs or simply due to friendship. Depending on the purpose of their creation, networks are made up either of related persons who share a desire to spend time together (common concerns) or from people with other common interests, which usually dissolve when those interests change.

To identify the main sources of creating informal networks a first step was to identify the main differences between the formal and the informal networks of business organizations; Table no. 1 summarizes these differences.

Table no. 1 Formal networks vs. informal networks in organizations

Elements	Organisations	
	Formal	**Informal**
Objectives	Organisational	Individual
Structural components	Functions/offices	Individual roles
Information feeds/Level of communication	Function of formal position	Function of proximity/approach: physical, professional, social, formal
Level of authority/power	Legal authority	Capacity to satisfy the individual needs (usually through an expert)
Control mechanisms	Rules	Norms
Hierarchy	Vertical	Lateral
Individuals membership	Specific	Ambiguous
Communication	Structured	Unstructured
Origin	Plannned	Spontaneous
Group leadership	Explicit	Tacit

Source: adapted Han, P. E. (1983), The Informal Organization You've Got to Live With. Supervisory Management, 28 (10) 25-28 and Farris, G. F. (1979), The Informal Organization in Decision-Making Strategy. International Studies of Management & Organization, 9 (4), 37-62. in Waldstrom C., (2001), Informal Networks in Organizations - A literature review, DDL Working Papaer No. 2

The two forms of networks (formal and informal) are interrelated, each completes each other; both influence the behaviour of individuals and are strengthened through culture, history or other factors of influence.

Moreover, starting from this composition of networks a question arises: why do individuals form informal networks and relationships in an organization? An intuitive response is that people are social beings even when placed in a formal setting, i.e. at work (natively rational individuals tend to constitute in networks to protect themselves, to get more power, to solve common problems etc.). Almost invariably rational individuals will tend to organize themselves in various types of social networks (whether formal or informal). From the perspective of each individual, as a "social actor", the membership of a network and the position of network member mean meeting certain needs or obtaining some benefits.

To identify the sources of constitution of the informal networks within companies, it is appropriate to recall the six sources of creating the identity of the individual, according to Huntington (2004); this is

the macroeconomic view social regarding the social capital and the values in which a person really believes (Huntington discusses the following sources: ascriptive, cultural, as religion or language, territorial, political, economic as profession or company; and social, which include friendships). From a microeconomic perspective, we deduce that particularly, the economic and social sources underpinning the construction of individual identity will be included as sources of constitution from the basis of informal networks of various organizations (making this statement does not exclude the influences related to the origin of the person, culture, politics, etc.).

Two authors who have examined closely the sources of formation of informal networks in organizations, namely Baker (1981) and Han (1983) suggested the following classification of these sources:
1. The need for affiliation. To satisfy the need of belonging to a group, the individuals tend to join friendship and support networks; this makes the individual's freedom of action limited, subjected to constraints or norms / rules of behaviour.
2. Identity and self-esteem. Belonging to a group or an informal network can develop, strengthen and confirm individuals a sense of identity and esteem due to personal interactions.
3. Social reality. As formal networks provide a limited framework of expression of feelings, emotions and personal way of thinking, informal networks can serve as an "agent" of structuring and supporting a common social reality; thus, the individuals can reduce uncertainty and stress. Also, informal networks can compensate feelings of dissatisfaction regarding the formal leader, the organization or the organizational communication system.
4. Defense mechanism. Group cohesion can act as a mechanism to reduce uncertainty and as a force of each individual to respond to a threat.
5. Risk reduction. Unconscious efforts of individuals to control the conditions of their existence lead, most often, to the creation of informal groups. Thus, by aggregating benefits and reducing costs, individuals perceive less risk as a member of the group, than as an individual.
6. The need to know. One of the primary characteristics of informal structures in organizations is their communication network, often compared to a "vine" (grapevine). Studies have shown that this type of communication is surprisingly accurate and quick; in situations where information is critical for a person, the "grapevine" communication can become an effective tool for gathering information, thus avoiding the formal channels of communication.
7. Need of help, support and power. Satisfying common interests such as position in the organization, wages or other issues.

Given the issues invoked synthetically in table no. 2 we present the most important sources of formation of the informal networks in companies and / or between the company and other external entities.

Table no. 2 Sources of informal networks

Affinity Friendship, trust and interpersonal relationships	**Political** Influence, power, authority
Technical Consultancy, professional / technical information exchanges, knowledge and innovations	**Cultural** Values, information flow and communication

Source: adapted Waldstrom C., (2001), Informal Networks in Organizations - A literature review, DDL Working Paper No. 2

So, from our point of view, the informal networks are primarily based on trust between the actors, common interests and / or benefits expected by all members of a group of employees / individuals; such informal networks involve regular exchange of information periodical/ permanent and certain networks of communication between the group members. A first source for the formation of informal networks is that given by the bonds of friendship / affection / collegiality that typically occur between partners who have equivalent status (homophily).

Secondly, we can discuss a political approach regarding the establishment of informal networks which refer to individual and group goals; thirdly, a technical approach involving work-related relationships and form around people holding technical or professional power in an organization; and not least, a cultural approach, resulting in the way of transmission and sharing of tacit and implicit values of the organization.

In the management theory is an unequivocal distinction between a group of employees and a management team; switching from a group to a team takes time, a proper leadership and the gradual building of a climate based on the trust between the members composing such a structure. From the perspective of social studies and various angles on social capital, it is not very clear how certain informal relations differ from group to group within an organization (group cohesion, team spirit, the characteristics of an effective team, etc. are addressed relatively confusing in studies) (Avram, Shockley-Zalabak, 2008, p. 242-257). However, it is recalled that informal relationships between "n" employees (a service, office, etc.) can assist in building effective management teams to the extent that is based on friendship and fellowship at the workplace; such relationships can evolve beneficially from an "informational" guy to a "special" guy, as it strengthens trust between the members of such a structure. In table no. 3 we summarized the three types of relationships between members of a group of employees and the benefits that can be developed in time to support the organization's performance.

Table no. 3 Relations of friendship / fellowship between the members of a group of employees

Functions	Information relations	Collegial relations	Special relations
Primary functions	Share of information	Career strategies Professional relations Feedback Friendship	Confirmation Emotional support Personal feedback Friendship
The level of commitment	Asks little, but offers many benefits	Share of information while trust is growing	It's equal to “the best friend“
The intensity of the relation	Social, but limited in sharing personal experience	Allows an enlarged self expression	Powerful aim of relation
Work results	Increases the individual's attention regarding the activity/work of the organization	Limited support for the exploitation of the discussions about family and work	Large availability for support and for work results
Satisfied needs	Source of information regarding the career opportunities	Gives direct and honest feedback	Offers the chance of free expression of personal and professional dilemmas, of vulnerability and personality

III. Informal networks between individuals and / or between organizational groups

Since a large part of the theory in business administration / management has not addressed solely the issue of informal networks / relations, we resort to a general analysis on these structures. In our opinion, we must underline in the beginning the idea that there is no preset pattern (and possibly known / reviewed in management theory) based on that describes how they arise, evolve and reinforce various informal relations and informal networks more or less stable between "n" members of an organization. Therefore, it must be concluded that certain methodological tools that sociology and organizational psychology (sociogram, communigram etc.) suggest and which are useful in the analysis of informal relationships need to be customized for a specific type of company / firm.

From the perspective of general approach in sociology, we will discuss about two known issues in this area (Hollander, 1978; Rabajante 2009 etc.):
a. The notion of sociogram constituting a sociometric instrument and shows us the graphic pattern at the time of forming a group and / or in the context of the development of a social group; simply put, the sociogram is the graphic representation of the relationships that may arise between "n" individuals when they inter-relate, voluntarily or not, as "actors" of a social group. The theory argues that sociogram plotting to capture informal relationships in a company constitutes in an extremely useful tool when there is a KM strategy and seeks to maximize the flows of knowledge / information for all departments that make up the organization chart. The classic version of the sociogram for "n" actors that make up a group of people locate in the center of the graphic structure a person or a sub-group that will play the role of "node" (later we will discuss the role of hub and others); other persons or sub-groups according to the intensity of the relationships or other characteristic regarding the "node" will be distributed concentric in a certain distance from the central area of the entire structure (each will be referred as isolated, rejected, etc.).

From a theoretical perspective, drawing a sociogram for a certain group of people requires an administrator and establishing some criteria that are presented to the participants in such proceedings; there are certain aspects regarding the drawing of a sociogram among which we mention:
The concept of reciprocity between two members of the group and that is the binder that gives cohesion to any social group (we are talking of confidence as a basic element of the social capital, but we also invoke the notion of reciprocity);

The concept of empathy between two or more members of the group that relates to the way a person perceives / understands the other and the expected behaviour of others;

Other notions or concepts that are used by sociologists to describe the relations between the "n" individuals forming an informal network (the distance between some members of the network to its center, the criteria by which we can associate members, the duration in time of some relationships that occur between various members etc.)

b. From the perspective of any social group, we mean that such groups are established and operate under norms / rules that are accepted by the members of that structure. After drawing the sociogram for any group, there is the problem of identifying communication channels between the members of groups and various types of network communication that can occur in this respect. Thus, the communigram is the graphic structure of communication relationships between the members of a group of "n" people; theoretically, the decentralization of communication networks is recommended to ensure all stakeholders an equal access to knowledge and a good position in the group structure. Among other issues, we observe that any informal group that represents a company and / or society is based on communication between the "n" members; the lack of communication channels and the process itself leads to the disintegration of the informal group (simply put, it is hard to imagine the existence of a social group of "n" members, for which there is or not a drawn sociogram, in the absence of some usual processes of informal communication among members; the pattern of these communication channels has also the shape of an ad hoc network, that can be associated largely with the pattern given by the sociogram). According to Johnson, the communigram would constitute for that matter a special kind of sociogram of an informal group and he shows us the pattern of the relationship of communication between the members that make up that group; in recent years there have been developed several software programs to design / simulate the communigram of some companies as a graphic network that takes into account the channels of informal communication between individuals and groups (Johnson, 2009, pp. 38-39).

Mintzberg (1999) suggested that since the 90s there is no specific way to identify and interpret these networks / informal relations which are established and evolve between "n" people; however, a number of common elements intervene (they are in direct contact with the instruments promoted by sociology to study / analyze the informal relationships) respectively the nodes (sometimes called

actors, sub-groups or individuals etc.) and relationships / links between nodes of a particular structure (sometimes relationships are called links).

IV. Knowledge and management of informal relations

When discussing about knowledge as a distinct resource of the organization and about building a formal / informal network to create and exploit knowledge the tasks of a company's leadership become more complex. This is because the strategy in KM (Knowledge Management) and that of HR (human resources) should take into account the employees' tendency to form in informal networks (ie hypothetical advantages and disadvantages for the organization).

In our view, the conversion of explicit knowledge into tacit and vice versa through mechanisms of socialization, externalization or other similar ones can be facilitated by various informal networks that constitute between employees when they have a common and positive purpose for the company. Consequently, the work of creativity and innovation of the company can be enhanced in turn, if it facilitates access to new information and their conversion between different classes.

In Table no. 4 we present the relationship proposed by Johnson between knowledge networks (KN), creation, transfer and implementation of knowledge in business organizations (Johnson, 2009, p. 173).

Table no. 4 KN and creation, transfer and implementation of knowledge

The content of the knowledge network	**Stage/point**		
	Creation	**Transfer**	**Implementation**
Explicit and tacit knowledge	Tacit	Mixed	Explicit
Key role	Novelty	Contagion	Influence
Equivalent status	Low	Broker involvement	High
Differentiation	High	Moderated	Low
Integration	Low	Slow link	High

Source: adapted from Johnson, Managging Knowledge Networks, Cambridge, Uk, 2009, p. 173

In Johnson's view, certain aspects are specific to informal networks that arise in organizations and join closely with KM strategies for the acquisition and conversion of knowledge; in the view of this author we must distinguish between certain elements of a knowledge network (KN), understanding that this network is associated largely with the informal network of "n" employees; the considered elements are (Johnson, 2009, pp. 150-173):

- The KN content: is given by explicit and / or tacit knowledge which is distributed in the structure of the informal network (part of it may also have official character);
- The key role that a KN actor plays: is given by what we called "node" and / or "hub" of an informal network (most often in this form we will meet an expert on a particular field, but it can also be in knowledge manager, knowledge engineer, etc.);
- "The status equivalence" (Homophily) represents the native trend of individuals to interact with others who are similar as status, religion, education and other social issues (in some cases proximity between two different social groups as status can occur through a knowledge "broker"; we previously discussed about the gatekeepers and pulse takers that occur in the operation of a normal informal network, any of this category of employees can take over the duties of a broker);
- Differentiation within the KN shows the different role that falls to some groups of employees or structures set up to exploit knowledge on a competitive basis (same competition may be based, however, on cooperation between members and it is especially necessary for sharing tacit knowledge; cooperation can be formal or informal according to the organization's KM strategy);
- Integration in KN: is the opposite vision of what can be achieved through differentiation in the acquisition and sharing of knowledge (primarily through the informal networks but also with the involvement of some formal / official structures; the realities in a company do not allow

"breaking" the informal networks from the formal ones, this can take place only in abstract level, i.e. methodological).

Finally, the issue of the report between a company's leadership and the exploitation of informal networks in the direction desired by the organization remains, we believe, a complex subject and insufficiently clear in the management theory. It is pretty argued that the effective leadership in a company requires interpersonal influence, vision and a model of positive behaviour for others; various categories of executives have a certain power and role in learning and sharing information / knowledge (Mintzberg, 1984).

In this view, leadership is visible in positive and innovative behaviours' of employees such as: new ideas and processes; the participative management style, we say, is crucial in these processes. Moreover, in terms of change, leadership is the force that spreads the "seeds" of a motivating environment for the other employees; it becomes a mediator, an "actor" that promotes and transmits new convictions, ideas, vision and objectives etc .; above all, the leader gives collective confidence / faith for all or most of the subordinates who direct their effort consistently. Another issue that arises related to the position held by a manager and as far as he gradually becomes in time a genuine leader is the one that refers to the process of delegating some responsibilities / tasks to lower levels of the hierarchy; is unclear, we believe, how should the process of delegation be carried out so as to valorize the informal relationships that already exist between the subordinates. In our opinion, it is ideal when executives of a company support the strengthening of some positive informal relations between subordinates and moreover, take into account such relationships in the process of delegation, creation of task force teams or other similar directions of action. According to the opinions of Thorlakson and Murray (1996) the simple empowerment of the employee is not the guarantor of knowledge transfer and the generation of innovative processes; a good communication, team cohesion, a flexible management style are the decisive factors.

In summary, the main contributing factors, we believe, to the formation of optimal informal relations and with implications on the organizational performance are:

- The quality and the type of leadership applied at top and middle management;
- The commitment and dedication from the management (demonstrating a responsible, credible, competent and fair behaviour);
- The coaching from the management (directing employees to socialization processes and other mechanisms for knowledge sharing through formal / informal networks);
- The participatory management and positive behaviour patterns applied by various executives (gradually, through persuasion, perseverance and patience);
- Building confidence over time (management of change).

V. Conclusions

From the perspective of managing informal networks, we believe that this raises a number of implications for the management; first of all, the mere fact that managers are themselves involved in a variety of informal networks (in and outside the organization); secondly, the informal management structures are intrinsically alternative / temporary - since different people with different skills are required by a number of individuals at certain times, the informal leaders tend to be "temporary" and always changing to meet the various needs of the group. Thirdly, the informal background of manifestation of the influence and the power can prove to be a real "laboratory" to test the skills of future managers to maintain a balance between formal and informal requests. Moreover, Johanson (2000) and Simon (1969) pointed out that informal networks tend to develop hierarchical structures, thus creating the need for informal leaders; also, unlike the formal structures, in the informal ones, the most important people or subgroups of people are not from the top, but those at the center of clusters / groups of interaction.

Therefore, given the issues, there can be suggested certain strategies for leadership, to build and strengthen informal relations with positive impact to the overall strategy of the organization:

- The gradual establishment of a climate of trust by the decentralization of communication networks and free access to knowledge / information and by the tools to motivate groups and management teams (jointly motivation will generate jointly interests and benefits);
- Periodic analysis of informal relations that constitute in time between employees and / or departments from the organizational chart by conducting studies on sociogram, communigram and other patterns of informal / formal relationship; first, the type and nature of informal relations must be known (whether there are excessive conflicts between the groups; what is the level of organizational stress, which persons are compatible with each other via status, social position and owned expertise, etc.), because only later on these relationships to be enhanced by the superior decision maker;
- It is relevant what Fukuyama (1997) states: in organizational context, social capital and social networks should be associated not with the ability of individuals to work under the authority of a person or a group, but rather to their ability to form new relationships and to cooperate in new terms of reference.

Abstract

The development ofthe importance of space systems and capabilities in the functioning of critical infrastructures has led to the point where some space systems themselves can be considered critical infrastructure or critical components of the system-of-systems. One of the most important set of applications is related to resilience governance, where space systems might eventually play an outsized role. This is leading to a critical dependency issue which will generate new risks and vulnerabilities, in addition to the expected benefits. The present paper proposes a generic model of crisis oriented resilience governance with full spectrum use of space capabilities as an illustration of what can be achieved, exemplifying each step with real world inspirations and underlining other interesting dynamics, such as the security risk borne of the growing dependency on space systems themselves.

Keywords: space systems, resilience governance, critical infrastructure protection

Introduction

Since the launch of Sputnik, the first manmade satellite, numerous systems have been placed in orbit to provide specialized services to a growing body of users and, ultimately, an even wider array of beneficiaries. Space capabilities range from communications, positioning, navigation and synchronization to Earth Observation and are key enablers of a wide range of applications, such as precision farming, the management of global supply chains, the management of global financial markets and data flows... Critical Infrastructures (CIs) are socio-technical assets, systems and organization, both small and large scale, whose disruption or destruction would cause material and human losses to society and might even lead to reverberations throughout other interconnected systems,as stated byMoteff et al (2003). The European Union's Program for Critical Infrastructure Protection acknowledges such critical infrastructures as transport, energy, food supply, health, education and others. More and more all these infrastructures are integrating space capabilities into their functioning. They, themselves, constitute a system-of-systems. Muresan and Georgescu (2015) explain that in the meantime, space systems have reached a level of importance in the functioning of critical infrastructure system-of-systems that they can be described as having achieved criticality, and become critical infrastructures in their own right. One of the main applications of a wide array of space capabilities is in crisis and emergency management, in a narrow sense, and resilience governance at the level of societies and groups of societies in the wider sense. Resilience is the ability of a complex system, such as a human society of varying sizes, to withstand the harmful impact of unexpected negative events while mitigating the damage caused and enabling the rapid resumption of a normal state of functioning,as per Vugrin et al (2010).

Critical space infrastructures vs terrestrial infrastructures

Critical space infrastructures differ from terrestrial infrastructures in a number of ways:

- There is a significant economic barrier of entry to developing infrastructure in space, relating to the cost of the system and of its launch;
- The marginal productivity of a new space system unit must be very high to justify the cost, meaning that the number of satellite units in space is often the minimum required to meet demand, reducing redundancy;
- Thus, their criticality is increased, because every satellite is used to its very limit for maximum efficiency and gain. There is little extra or reserve capacity for the provision of critical space services. Easton (2015) is stating that even the American military, which does not have the constraints of private actors, must route 90% of its communications through vulnerable civilian systems because of insufficient military satellite capacity. Efficiency itself is, to some extent, and anti-resilience concept, since it often means setting up a system with the illusion of the permanence of ideal circumstances (just-in-time inventory provisioning etc.).
- Replacing space systems is also costly and time consuming;
- A lack of standardization and interoperability because of limited weight capacity for missions, leading to specialized units whose functions are neither easily replaced nor easily supplemented. Another consequence is the current lack of refueling capability, which limits the useful lifetime of satellites even when the components themselves are still operational.
- Space systems are expected to be continuously active in one of the most hostile environments known to man, replete with kinetic and electromagnetic threats which occur on a daily basis, leading spontaneous malfunctions being a common occurrence;
- While space is a vast area, the dynamics of orbital movement and the global distribution of demand for space services mean that most space systems are clustered in orbital bands catering to the most important space faring countries and consumer markets. This means that collisions with debris are a real possibility, and even collisions with other satellites, active or inactive. This uncertainty adds to the cost of developing and operating space systems;
- A majority of space systems are dual use, meaning that they have also military applicability, which complicates the issue of access to technology, regulated usage and other forms of restrictions. For instance, the American GPS system is a military project and, while civilian use has been encouraged and greatly expanded in the last few decades, the military reserves the right to regulate or terminate service to civilian users, even in nations allied to the US, should the strategic situation warrant it. The European Galileo system was developed with the express goal of excluding any provision that may limit normal and legitimate use.

There are also concrete and specific threats to critical space infrastructures:

- Space debris – the accumulation in orbit, due to natural processes or human activity unregulated to minimize debris production, of objects ranging from a few millimeters in size to whole satellites which constitute a collision hazard. While there is a natural process of atmospheric re-entry, it is viable only in low orbits, and, for all intents and purposes, space is one of the least regenerative environments known to man. The most active and crowded orbits are also some of the most dangerous and come to resemble minefield, where even whole satellites may collide with each other at hypervelocity;
- Space weather – a term describing the charged particles, radiation and other phenomena which result from solar activity or are present in the ambient space environment. According to Baker they represent major threats to satellites and other space assets, which are routinely damaged or destroyed by highpoints in the solar cycle of activity. Even terrestrial infrastructures are affected by space weather, damaging power grids, interrupting communications even through land-based systems and being able to damage systems which depend on electricity and circuitry – meaning all systems, especially through the potential for cascading disruptions. As per Royal Academy of Engineering, efforts at hardening both space and terrestrial systems are necessary to prevent the

grave losses that can be incurred by space weather phenomena at levels previously recorded in history, before mankind was so vulnerable;

- Manmade threats, as described by Grego in "A History of Anti-Satellite Programs",as deliberate human threats to space critical infrastructures are many, varied and highly efficient. Their development dates back to the beginning of the American and Russian space programs, which had an important military component and a "dual-use" philosophy regarding the development of new technologies. Gheorghe andVamanu(2007) stated that many actors in the field of space develop anti-satellite systems of legitimate technologies for protection that can be modified to become efficient anti-satellite weapons. They range from the easiest and most cost accessible means of inflicting damage (cyber attacks, jamming of ground station) to highly sophisticated missiles or laser attacks which blind sensors or destroy satellites entirely. Some of the anti-satellites capabilities are predicated on replicating the effects of the specific threats above, like electromagnetic pulse (EMP) strikes replicating space weather phenomena, and kinetic attacks both destroying space assets and creating new debris that act as a minefield.

The generic model of resilience governance

Resilience governance complies a complex set of tasks, such as the gathering of data, site selection, risk assessments under an all-hazards approach etc. Space systems are an increasingly utilized tool in all of these instances, with Earth Observation capabilities becoming not only more advanced, but also more accessible as pricing and business model.

In the past, integrating space capabilities towards a generic model of resilience governance has been constructed piecemeal, through incremental addition of new applications and new service capacity. Based on this experience, it might be possible, in the future, for a country or a security actor to develop its resilience governance system, from the ground up, within a space paradigm.

The major components of this system follow the natural course of a crisis and emergency situation, which has a before, during (in progress) and after phase where specific processes must be attempted that involve space capabilities.

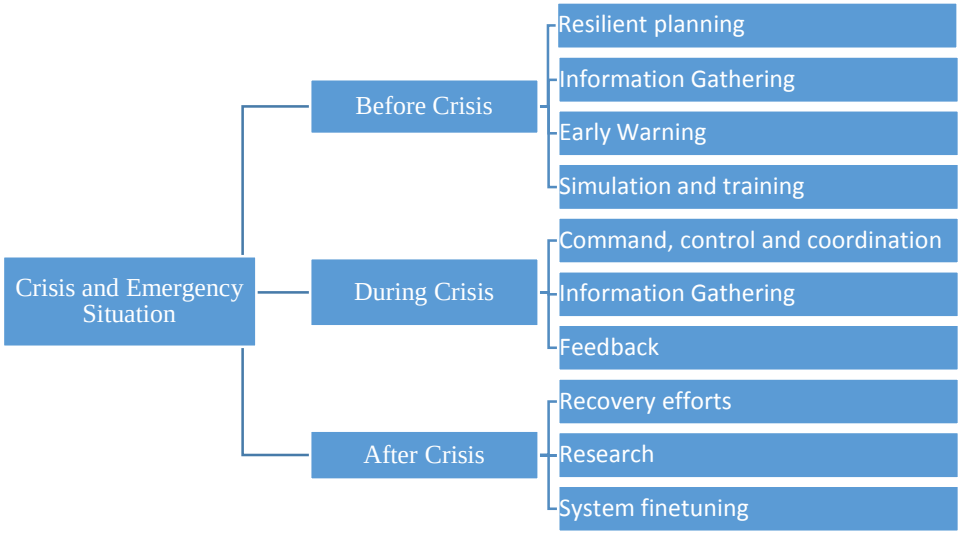

Fig.1 Space capability implementation within crisis management

Fig.1 is especially useful as a guideline for space capability implementation in sectorial threats, and the actual examples given will be selected with a bias to particular sectors that underline the seriousness of resilience governance.

The before phase – while it may only be a rhetorical flourish to claim this as the most critical phase of a developing crisis and emergency situation, it is evident that, for a generic threat, the proper implementation of resilience governance components during a before phase can either prevent the materialization of a negative event or minimize the level of damage and disruption to normal activity that it would generate. Space systems are a critical addition to these processes and can be reliably integrated into them.

Resilient planning component– before the generation of risks, vulnerabilities and threats, there is a development process for the critical infrastructure whose resilience will need to be assured. Critical infrastructures form the bedrock of societal development at economic, social and political levels, and their planning, development and implementation increasingly reflects precepts developed under Critical Infrastructure Protection (CIP) research, with the goal of minimizing threats and maximizing desirable traits that have been defined so far – resilience, robustness, flexibility, interoperability, graceful decline etc., as stated by Hokstad (2012). This line of thought is applicable not just to technical assets, like power plants, factories and ports, but also to organizational infrastructures, like national defense and public administration, which both the American and European frameworks for CIP recognize as critical infrastructures.

Information gathering – during the functioning of critical infrastructures, space systems can be employed for continuous and low cost monitoring of the site and assessing the potential for changes in the underlying environmental conditions of the site's area, in the larger definition of environment, which includes various elements and phenomena. The space systems also enable a wider net for information gathering, with their capacity for observing larger areas and for enabling integration of numerous data points from other users, adding a new dimension to the more parochial paradigm of in-situ monitoring. According to Hame (2013), nuclear waste repositories can be continuously monitored for natural events or for attempts at terrorist or criminal subversion.

Early Warning – the frequency with which space systems enable monitoring, in addition to their capacity for sustained research, also enable the identification of threats or trends that can lead to the threats. Ultimately, this leads to early warning capacities which are vital for the minimization of damage and rapid resumption of normal functioning. Weather satellites may spot the formation of a hurricane or other extreme natural phenomena. On the human side, satellites are used by the Comprehensive Test Ban Treaty's International Monitoring System to detect preparations for nuclear tests, activities related to nuclear proliferation which are considered unlawful and to verify breaches and produce incontrovertible evidence in a passive way which is politically acceptable, as stated by Jasani (2014).

Simulation and training – the requirements for the build-up and maintenance of the active component of a resilience governance system also include the training of personnel and the running of simulations and scenarios for the refinement of protocols and procedures and the sharpening of reaction times. Space systems will naturally be a component of these processes, since their success depends on simulating the existing environment, in which both the infrastructure system-of-systems and the resilience governance apparatus itself utilize space capabilities.

The phase during the materialization of a negative event – space systems are an increasingly important tool in the actual management of a crisis event, providing information gathering and communication capabilities. With regards to our model for crisis and emergency situation, the authors identify three key components to which space systems are contributors or even main elements.

Command, control and coordination – certain events, such as disasters and terrorist attacks, may undermine ground based communication systems. Coupled with the necessity of coordinating field assets, there is a resulting need for reliable communication that is far removed from the crisis event in question. Space systems provide the adequate vector for asserting the role of the chain of organization and maintaining the upper view over the crisis and the decision makers' response to it. For instance, during the Fukushima nuclear crisis precipitated by an earthquake and tsunami event, satellites such as Kiku-8 and Kizuna provided crucial connections to response teams and to municipal and national authorities.

Information gathering – real-time reconnaissance by satellites is crucial for the modern approach to crisis and emergency situation management process, though it should still be supplemented, to the extent possible, by "boots on the ground". During the Fukushima crisis, Earth Observation satellites provided key readings of flooding and radiation levels, GPS signals and ground stations were used in conjunction to measure tectonic activity – crustal deformation and ground subsidence. The use of space system capabilities can be tailored to the individual requirements of each negative event.

Two key issues stand out during the Fukushima crisis and the employment of space systems by the competent authorities, as said Iwasa within "Disaster monitoring activities in Japan". The first is that it provided a vivid example of the reliance on space systems and how this growing dependency creates new risks, vulnerabilities and threats, which will be described in a later section. The main Japanese Earth Observation satellite with instruments adequate to this particular event, ALOS, spontaneously malfunctioned just after the disaster, depriving the decision makers of the provision of its critical services. The second is that this loss was made up for by the use of other Japanese satellites, but primarily by international partners allowing information sharing from their satellites.These types of cooperation are increasingly necessary and common throughout the entirety of the space services industry, because of the basic characteristics of space systems as an infrastructure – their cost, their versatility, their vulnerability and their difficulty of replacement, as well as the rapid advance in demand for their services.

Feedback – as a composite process, it includes elements of the previous entries in this subheading, but the authors chose to illustrate it separately because of its conceptual importance during a crisis or emergency situation. Space systems are becoming an important backbone of the feedback loop that keeps decision makers up-to-date not only with the crisis environment, but also with the results of prior decision and actions, enabling them, almost in real time, to shift resources allocation, change tactics, correct errors and respond to both foreseeable and unforeseen challenges.

The post-crisis phase – involves not only efforts to reestablish business continuity and quality of life, and recover from damages, but also the important processes through which future negative events may be avoided or their impact lessened. Often, these final processes are neglected in favor of the often arduous recovery, but they are vital for long-term improvement in the resilience of the system-of-system. Space capabilities play an increasingly important role here as well.

Recovery efforts – even after the urgency of the crisis situation has passed, space systems use is warranted to speed up the recovery process by providing information, assisting communication and coordination and providing replacement capacity for damaged terrestrial systems, such as landlines for communication or ground station instruments for monitoring. Should military assets be deployed to assist in early phases of the recovery, such as clearing debris, providing aid and logistics or preventing a breakdown of public order, then space systems assume a greater role in the short-term maintenance of national security, by enabling maritime border surveillance, monitoring activities of other military forces or other applications.

Research – space systems permit cost effective forms of monitoring which can provide researchers with a better understanding of the consequences of the negative event, or allow them to prepare for a negative event by ease of access in studying sites for other, similar events. For instance, after the Fukushima

Crisis, Japanese researchers began collaboration with Ukrainian counterparts for the study of the Chernobyl Nuclear Power Plant area to understand the long-term implications of the release of radioactive materials in air, soil and water, as stated by Yoshimoto (2013). This research will be important for the recovery of the Fukushima area and the refinement of security and civil protection procedures, as well as mitigating as much of the long-term damage as possible.

System fine-tuning – as a direct result of the research stated above and the impetus given by the recovery efforts and the determination to increase societal resilience, the resilience governance system may receive a fine-tuning to which space systems shall contribute and of which space systems shall also constitute a greater part as the next frontier in resilience assets. This also fits in with the trend to take advantage of the technological and price availability of nanosatellites system capability to launch more systems and create economies of scale, redundancy, substitutability, more rapid replacements and so on. Four of those systems are of the Hodoyoshi line. It is very likely that Japanese development of space systems in support of resilience governance will not end here, and further development will lead to a more intricate interplay between ground assets of the national disaster response system and other resilience mechanisms and space systems. The resulting state-of-the-art and best practices will then be a model to other actors.

The authors notice that the model proposed above is not a straight line just because it is set in chronological order. It is actually circular, and the final processes of the last phase of the resilience paradigm will blend seamlessly with the first processes of the pre-crisis phase for the next societal upheaval.

Model's limitations

The paradigm must be completed conceptually through the acknowledgement of a significant aspect of Critical Infrastructure Protection theory, whose study and mapping is being formalized as the development of the discipline-of-disciplines Infranomics – the interdependency between critical infrastructure systems which leads to the risk of cascading disruption of their functioning. Moreover, this interdependency is not linear, but node based, resulting in every infrastructure being influenced, to varying degrees (both in a conceptual and circumstantial manner), by many other infrastructures. The cascading disruption, failure, or decline feeds on itself through this web of relations, leading to a vicious cycle where one infrastructure's decline rebounds back to it to amplify its dysfunction and the subsequent contagion, as states Katina and Hester (2013).

Due to interdependencies between countries with regards to their provisioning of space services and the factors described above which limit the number of space systems, there is an important deterrent against formal militarization of space and the use of space as a vector for conflict. Long (2008) mentioned that The Rand Corporation has described a logic of "mutually assured destruction" that prevents countries with ASAT capabilities from making more than token shows of force, especially if the particular ASAT technology is the kind that would affect the global commons, such as EMP weapons or debris generators. Rogue states and non-state actors are left in this situation with both the inclination to use ASAT weapons and a lack of responsiveness to the normal logic of deterrence. While not all ASAT means are at their disposal (with the exception of North Korea's space program), there are options, such as cyber-attacks, that present a very good cost and risk ratio to gains.

Conclusion

Space systems are an important tool for resilience governance because of unique capabilities. They provide significant services in all stages and processes of response to a crisis and support decision makers in long-term efforts to increase the resilience and robustness of society, enhancing quality of life and

business continuity. The authors have sketched a paradigm of resilience governance with full utilization of existing space capabilities, whereas, currently, there is a haphazard approach towards integrating space capabilities in the decision maker's toolbox. Over time, the lowering of the cost of space systems, the cost of access to space services and the increase in the quality of rendered services will lead to a more widespread use of space systems in resilience governance with all-hazards approach. Meanwhile, we must be mindful of the characteristics of space systems, which have their own risks, vulnerabilities and threats whose materialization may impact resilience governance processes because of established dependencies. Various means can be used to increase the resilience of the space systems and the resilience of the systems integrating space capabilities, both technological and organizational. The trade-off seems worth it, given the variety of threats which are more easily managed through the use of space capabilities. In developing this paradigm of resilience governance based on space capabilities, a concomitant dependency on the proper functioning and availability of these space systems is also being nurtured. The concept of *criticality* which has been developed for infrastructure systems is also applicable to space systems, to the extent where they themselves can be considered critical infrastructures. The criticality of space systems is evident across multiple fields, through the growing use of rapidly developing space capabilities, and is apt to be described through the existing means for assessing the criticality of terrestrial infrastructures. However, for the purposes of this paper, their role in crisis and emergency situation management and the larger process of resilience governance has been highlighted.

The more we move towards a realized version of the generic space-reliant resilience governance paradigm, the greater the benefits will be in terms of costs, efficiency and operational capacity. However, security decision makers must be aware that, while a net positive gain should be pursued, there are also security trade-offs, resulting from the exposure to generic or specific risks, vulnerabilities and threats of space systems. Rather than resilience being a destination for an evolving governance system, it ends up being a tightrope balancing act where security gains made through the judicious use of space capabilities are offset partially by the insecurity generated by the dependency on these systems.

Analysis of Start-Up Investments in European Region

Mgr. Katarína Rentková, PhD., Comenius University in Bratislava, Faculty of Management FM CU, Bratislava, Slovakia, katarina.rentkova@fm.uniba.sk

Mgr. Monika Roštárová, Comenius University in Bratislava, Faculty of Management FM CU, Bratislava, Slovakia, monika.rostarova@fm.uniba.sk

Abstract

An article deals with the issue of start-up financing. The aim of article is to analyse sources of start-up funding in European region according to available data and relevant statistics. The publication focus on several types of venture capital and investors associated with start-up financing. A contribution is an overview of important funding sources in Europe and their characteristics such as a type of invested capital, a purpose of investment, a stage of start-up life cycle, a share in company and a risk rate.

Keywords: start-up, investor, business angel, fund, venture capital, early stage

Introduction

European business environment has been changing in recent decade of years. Start-ups are a new phenomenon, which was firstly established in US. An article is focused on the financial forms of support, which are known and typically used in European region. Venture capital is the influential factor in European economy and we can recognise the contribution of start-up investments in GDP in particular European countries in the last decade of years. The research is based on a real case study and statistics collected by several associations of investors formed in European region. The article compares venture capital investments according to the source of investments, industry of investee and the form of venture capital.

Research objective

The main issue of this article is the start-up financing, especially the analysis of different sources of start-up funding in European region. The general subject is start-up; the problem is its funding from various sources. Currently, the issue of start-up devoted considerable attention in the academic circles, but mainly is based on the practice. Innovation, new ideas, technology development represent major challenges of contemporary society. But the question remains: "Where and from whom raise capital and investments for start-up?" There are many possibilities, so the article elaborates on the:

- The investors of start-up;
- The types of capital;
- The origin of capital.

Support and funding of start-up includes several important steps, and even the investors themselves must address certain important issues. Examples include the industry of investment or sector of investment. In Europe, the problem of startup is developing very quickly, so article solves current issues.

Objectives, methods and methodology

The research is processed by using a wide scale of the scientific methods and procedures. The specific range of methods was based on the research needs of the individual parts. The intention is to follow the logical continuity of the articles 'parts, the correctness and the adequacy of information and data. First part is focused on the definition of startup and on the determination of the cycle of start-up financing. This section is prepared by using the analytical methods – the analysis, the casual analysis, the synthesis, the induction and the deduction. The first part is based on literature review; it is based on available literature and studies.

Empirical research was carried out and is based on a case study which deals with investment in start-ups in the European region. This case study is based on statistics and surveys which were aimed at business angels and venture capital or other funds set aside for start-up. The second part is prepared by using scientific methods – the analysis (the secondary analysis, the causal analysis),
the comparison and the statistical methods.(Mitkova)

Article represents the basis of the planned long-term research which expected the use of more scientific methods such as the benchmarking and the SWOT analysis. It is expected to focus on the selected States and prepare more case studies of specific countries.

1 Literature review

Start-up *is an innovative organization formed to search for a repeatable and scalable business model.* The business model is the main factor of difference between the start-up and other new enterprises. (Blank)

Professor Steve Blank briefly describes features of start-up business model. *A company with a scalable business model is able to rapidly increase its sales and number of customers.(Blank)* Scalability is a condition that the volume of sales did not increase in proportion to the cost of the project. Otherwise, the company would not be interesting for investors. A repeatable business model is related to an income generated by the company. The business model is repeatable when the company is able to achieve revenue through its activities more than once.

From the point of accounting *start-up firms have usually a low total assets turnover till their incomes increase to the covering assets level from first round of investments (Komornik).* Turnover is directly proportional sales and start-up in first stages of their lifecycles don´t have any sales or incomes. Assets are restricted, but the first amount of assets is a key source.
The difference between a start-up and a small company is visible in the character of companies 'goals. Small companies focus on a profitability and a stable long-term value. Start-ups are based on a growth potential and incomes. Both of them wants to be profitable in the end, but start-ups need to attract investors. The profitable company doesn´t need any investor when we don´t think about the stage of expansion.
The cycle of start-up financing is connected with the start-up life cycle or the start-up development cycle. The amount and the risk of investment are based on the particular stage of start-up development. A capital is collected in several rounds according to: (Komornik)

- The likelihood of success
- The credibility of concept
- The growth of customers´ base

Venture capital is defined as a source of financing for new businesses. Venture capital funds pool investors' cash and loan it to start-up firms and small businesses with perceived, long-term growth potential. *Venture capital is the most important way of funding start-ups that do not have access to their*

own capital. Described capital entails high risk and potentially high returns for the investor. There are several types of venture capital and they differ in start-up's stage and amount of investment. Individual investors usually invest mainly one type of capital. (Slovak business Agency)

Pre- seed capital is used for financing of ideas and research project with the goal of building a successful company around it in later stages. Pre- seed start-up are working on the business model and description of value creation for future customers.

Seed capital represents sources used for a market research and all activities before company´s establishment. *Investor finances the testing of investee´s entrepreneurship with seed capital. Seed financings may be directed toward product development, market research, building a management team and developing a business plan* (Investopedia). A genuine seed-stage company has usually not yet established commercial operations - a cash infusion to fund continued research and product development is essential. These early companies are typically quite difficult business opportunities to finance.

"A round *is the first round of institutional funding and is made up by one or more venture capital investors. Assessment and size of capital in this round depends on the progress made, the quality of team and a qualitative estimation."(Slávik).* After the business has shown some of a track record, round A funding is useful in optimizing product and user base. Opportunities may be taken to scale the product across different markets. In A round start-up needs to plan a business model that will generate long-term profit.´

In **B round** the business continues to the next level after successfully finished development stage.
Investors help start-ups get ahead by expanding a market reach. In Series B, venture capitalists have more of vision around what the structure of shares will look like and they concentrate on obtaining strictly set percentage of shares. (Frenakova)

C round investors inject capital into the meat of successful businesses, in efforts to receive more a high return of investment. Round C is about perfecting, and continuing to scale fast and wide. Companies in round C focus on raising a single digit to hundreds of millions.(Frenakova)

Start- up capital is applied to overlap initial costs including purchase of new machinery and equipment, purchasing of technologies, development of technologies, initial costs for marketing etc. Start- up capital is used for financing of start-up for first two years of operation.

Growth capital represents a funding to the initial growth of company. The phase of financing starts when the final product is created and a testing stage is finished and validated by customers in comparison to start-up capital. Money from growth capital cover marketing costs and expansion. (Blank)

There are manifold classifications of venture capital, which vary by author. Some US authors and researchers in start-up field use the term early stage capital. Mentioned term is connected with the capital which has been used for first three years of company´s operation. Early stage capital divides into start-up capital and growth capital. We consider start-up capital and growth capital as two separated form of capital in this article.

Expansion capital represents the amount of money intended for expansion. It is difficult to support expansion just by using own resources. The term expansion is linked to opening new foreign markets with selling the same product or a new product development. Expansion capital is used for mentioned purposes.

Mezzanine (bridge) capital is a special form of capital. Bridge capital finances the step of going public and represents the bridge between expanding the company and the Initial Public Offering (IPO). IPO is

the first sale of stocks by a private company to the public. Mezzanine capital does not strictly belong to venture capital.

Three F: **Family, Friends and Fools** are important people who support the biggest risk, because they invest to a new business concept. They do not belong to typical investors because they offer a financial support for the realisation of start-up concept and start-upper's life being without expecting any return of their investment. The start-upper uses his own savings and 3F donations to create a minimum viable product in **pre-seed (idea stage).**

The European Trade Association of Business Angels, Seed funds and other Early Stage Market Players (EBAN) describe the **business angel investor** as *a high net worth individual who provide smaller amounts of finance from £25 000 to £250 000 at an earlier stage* in comparison to venture capital funds, accelerators etc. Angel investors usually put their resources into the innovative, scalable and repeatable business model to first versions of product, which are suitable for betatesting and market validation.

A venture capital fund is a *pooled investment that uses the money from third-party investors, such as investment banks or wealthy investors, to invest in business projects. (Papík)* Businesses that seek venture capital often carry more risk. They are either unwilling to pay the interest on bank or market loans or are unable to obtain them.

Venture capital can be provided in two basic forms. First of all, it's called seed capital funds that provide young promising projects without sufficient funds. The second option is itself risky investments. Search for businesses around that with the realization of his own project already started but need additional capital for expansion. *Venture capital funds are not the only providers of funds. Most of them have their own experts who advise prospective firms. An initial seed investment round made by a professional VC firm typically ranges from $250,000 to $1 million. (Blank)*

The European Research and Development fund supports innovations and start-ups in European region. *Small Start-up Grant Scheme supports the growth of new enterprises having less than 50 employees. The scheme will reimburse 25% of the wage costs, utilities and rent/leasing of equipment and production facilities for start-ups that have been operating for less than 3 years. The ERDF Small Start-up Grant Scheme Incentive Guideline is the official document governing this incentive and includes details relating to eligible costs, applicable aid intensity and State Aid regulations.(SBA)*

Crowdfunding *is a new way of investing to new ideas and start-ups. It is based on funding by a big number of people or simply a crowd. People often invest their money in small amounts via crowdfunding platform in website.*(Slavik) Many start-ups invest their limited own sources to create a crowdfunding campaign and gain money for next stages of their entrepreneurship.

Research questions

Which is the actual status of start-up investments 'flow in European region? Can we analyse the start-up investments in European region only by focusing on business angels and venture capital funds in form of venture capital? Is it important to focus the investment analysis also on the nature of industry?

2 Result

According to market statistical data from the period 2010- 2014 the number of European companies as equity investees has been increasing for recent four years. 5519 companies received the equity investment in 2014. More than 80% of mentioned firms belong to small and medium enterprises. The total sum of

private equity investments in Europe represents €41,5bn. Invested capital increased in comparison to recent years by 14%. Private equity investments divide into three forms:

- Venture capital
- Buyout investment
- Growth investment

The total European early stage investment market is estimated to be worth **7, 5 billion Euros**. **Business angels** represent the biggest share of the investment market with **5, 5 billion Euros** of investment, followed by the venture capital industry investing 2 billion Euros in early stages (pre- seed, seed, start-up capital and growth capital).

The importance of business angels to the equity capital industry has grown significantly in recent years. Equity from business angels and their associations is increasing and becoming more important than venture funds'equity in Europe. Raising money via crowdfunding platforms is popular with the public, but a crowdfunding investments 'rate is still very low. Experts in start-up field expect a significant growth in the next decade of years. Crowdfunding represented just 1% of early stage investment in European region in 2013.

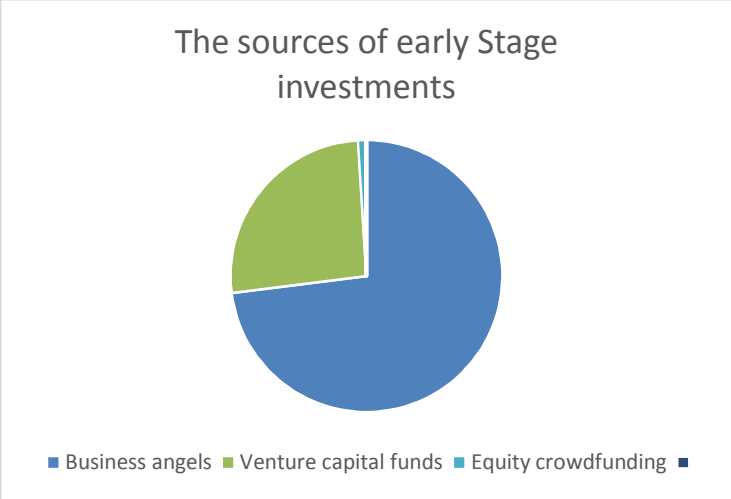

Figure 1: Sources of investments to start-ups in Europe 2013

Business angels are mostly successful entrepreneurs and managers. Some of them do their own PR activities and personally looking for start-ups. Others cooperate with investment clubs and networks. Business angels 'networks are often multinational.

On the other hand according to European statistics angel investors belong to global associations and networks, but they invest to companies in their home countries. Start-ups have a big chance to find investor in their home country.

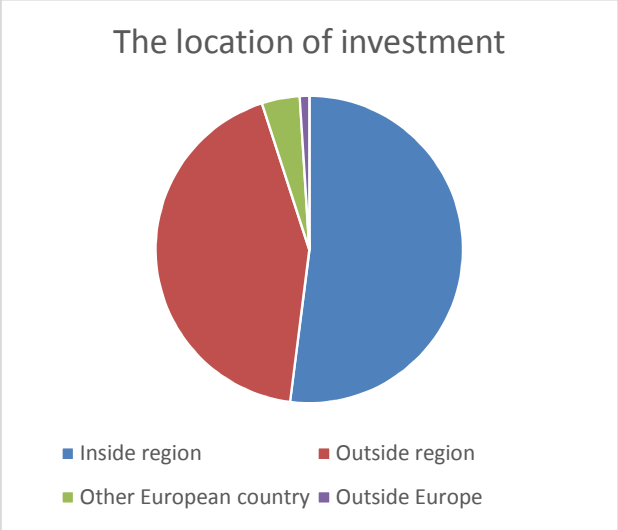

Figure 2: Location of angel investments in 2013 (made by data from EBAN)

Cross-border investment remains marginal as investments in the same country of the investor accounted for 96% of the deals made in 2013. Deals inside and outside the investors' region are 52% and 44% respectively. Investment in other European countries accounted for 4% of the deals while investment outside Europe represented only 1% of investments. (EBAN)

2.1 The character of particular venture capital types

The investment types of capital are illustrated on table 1, where they are connected to the stage and the purpose of investment. A rescue capital and an acquisition capital do not expressly belong to the venture capital. We implicated mentioned capital forms to the table just to illustrate the main differences among particular types of capital.

Table 1: ***Development stages of companies and the character of investment (made by data from Frenakova)***

Purpose of investment	Starting operation	Starting operation	Spreading Expansion	Spreading Expansion	Survival	Changes in ownership
Stage of lifecycle	Pre-seed Seed stage	Early stage	Early stage	Expansion	Maturity	Maturity
Type of capital invested	Pre-seed Seed	Start- up	Growth	Expansion capital	Rescue capital	Acquisition capital Mezzamine
Duration in years	7-12	5-10	4-7	2-5	N/A	2-4
Return of investment	80- 100%	35- 70%	30-40%	25-30%	N/A	100% N/A
Share in enterprises offering investment	1-2 %	5%	10%	50%	N/A	100%
Risk rate	Very high	high	medium	limited	N/A	Very limited

Pre- seed capital and **seed capital** are added in the same category. Pre-seed capital is more risky and it is connected with bigger shares in investee´s company than seed capital. The table comparison was created according input data, where this two sources of capital could not be divided. The table illustrates the average results from pre-seed capital and seed capital both used for starting the operation of start-up. The duration is very long, because the investment is realised in the beginning of business formation and support the transforming process from the original idea to the real business model. In next start-up life stages, there are other forms of capital needed, but seed capitalists usually make several rounds of investments. The return of investment can raise to 100 % because of the long duration and a very high risk rate. Average shares in this stage are very small, because they mainly belong to individuals, who invest a very small sum of money. A few venture capital firms and accelerators investing in pre-seed and seed stage can achieve shares up to 30 %.

Early stage start-up are looking for **start-up capital** to overlap initial costs during first two years of operation**.** Venture capital funds, business angel syndicates and individual angels usually invest start-up capital. The average percentage of investor´s share is 5 %. The duration is from 5 up to 10 years, because start-up capitalists are connected to investee from the beginning of selling minimum viable products to first early adopters. The return of investment has a wide range from 35% till 70% caused by different amounts of invested capital. ROI can reach a very high level, because early stage has a high risk rate and the likelihood of failure is still high.

The average share 10 % in investee´s equity accompanied by a medium risk occurs in the **growth capital** investment. Money are used to cover marketing costs and to finance the first expansion of final product. The sum of investment is bigger than in previous forms of capital. Return of investment is calculated to 30-40% and the growth funding has been used for 4-7 years.

Expansion capital is characterised by a limited risk rate and a high share in equity represented by 50%. The expansion of product or market is very demanding of resources. Return of investment is due to mentioned reason the lowest in comparison to other forms of venture capital and it is represented by 25 – 30%. The expansion stage is the last one before considering IPO. The duration of investment is from 2 to 5 years.

2.2 The funded venture capital forms in Europe

Start-up capital is the most popular form of capital with European investors including both business angels and venture capital funds. The figure 2 illustrates shares of particular types of venture capital invested in Europe.

Start-up capital represents **54 percent of a whole sum of funded venture capital** in European region. The second position belongs to seed capital, which is the most common type of venture capital for 22 % of European investors. Pre- seed stage has a higher risk rate and unpredictable return on equity in most of cases. Only business angels who have a tendency to put their money into higher risk invest the pre-seed capital and they finance 11% of the whole European venture capital.

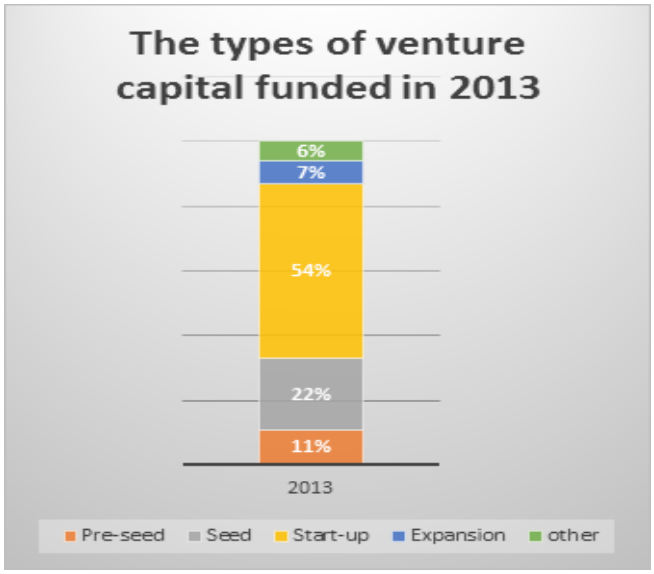

Figure 2: The types of venture capital in Europe

2.3 The industries of investments

Venture capital investors make the decision about their investees according to another important criterium – the sector or industry of investee. Mentioned factor is considered by business angels and venture capitalists both. The preferencies of particular investor´s types differ a little bit. Every investor decides according to his experience in industry, the economic situations of sector and different synergic effects.

Venture capital funds invest to companies mainly dealing with **life sciences**. Information technologies and Communications are almost equal in the second place. Other popular sectors are: energy and environmnent, Consumers goods and retail, Consumers services. Live sciences have a major s hare in venture capital funds´investments during the whole period between the year 2010 and 2014. The investment rate to ICT is stable, but trends in Communications are still slightly changing. Communication sector received more venture capital in 2014 than in 2013. That is a reason of the same possition of ICT and Comunication in 2014.

We prooved, that **angel investors** create the major share in European venture capital. Their preferences in the sector of investment are different. **Information technologies** represent by 33% of invested venture capital via business angels. Manifacturing reaches 11% percent of share. ICT forestall other industries very brightly and we can observe a huge difference between ICT and Life sciences and Communication represented by 10% both. Other popular sectors are: Health care, Energy, Creative industry, Retail and distribution.

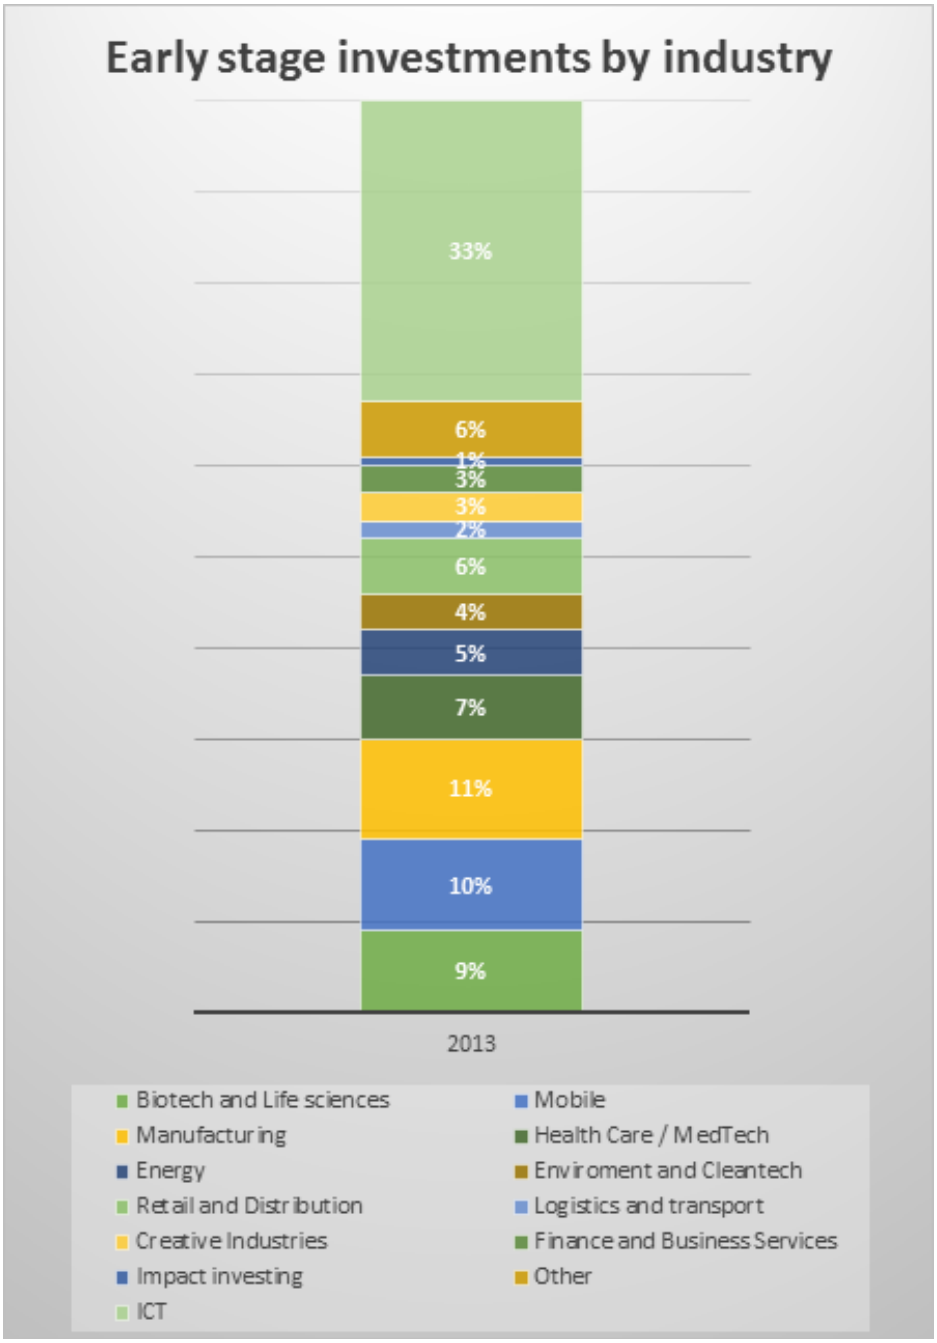

Figure 3: Fields of start-up investments in Europe according to data of Invest Europe Association

Conclusion

The publication analysed venture capital, start-up investors and the actual status of start-up investments 'flow in European region. We specified venture capital types, such as pre-seed capital, seed capital, start-

up capital, growth capital and expansion capital. We characterised typical start-up investors including 3F (friends, family and fools), business angels, venture capital funds and the users of equity crowdfunding platforms.

We focused on start-up investments in European region mainly made by business angels and VC funds in form of venture capital. The research data were based on two main statistics: The statistic compendium by EBAN and several statistical materials by Invest Europe Association. 75 billions of Euros were invested to early stage companies in 2013. 73% of European venture capital were offered by business angels. Venture capital funds invested less than 2 billions of Euros represented by 26%. The third position belongs to equity crowdfunding represented by 1 % of invested money of simply 80 millions of Euros. Business angels are the most influential European VC investors and 96 % of their finances flow to their home-country.

We compared particular venture capital types according to the value of invested money. Start-up capital is the favourite capital form, most popular with business angels and VC funds both. More than 50 percent of invested capital belongs to start-up stage. The rest of shares belong to seed capital (22%), pre-seed capital (11%), expansion capital (7%) and other forms.

The last part of results analysed industries, which had received venture capital investments. Venture capital funds invest to life sciences. Information technologies and Communications are in the second place. Other popular sectors: energy and environmnent, Consumers goods and retail, Consumers services. Information technologies represented by 33% of invested venture capital via business angels. Life sciences and Communication represented by 10% both. Manifacturing reaches 9 percent of share. Other sectors are: Health care, Energy, Creative industry, Retail and distribution.

Resume

Un des derniers rapports officiels d'évaluation du « système d'enseignement supérieur» explique sa défaillance par « la faible participation des acteurs » et le «climat à l'université ». Dans cet article, nous proposons une analyse théorique pour éclairer le débat sur la performance du« système d'enseignement supérieur». Nous proposons une analyse du « climat organisationnel » en mobilisant des travaux sur la théorie de la régulation sociale (TRS) de Jean-Daniel Reynaud, l'analyse sociologique de la notion de « silence organisationnel » avec les contributions de Morrison et Milliken, (2000).

Mots clés : performance, établissements d'enseignement supérieur, participation des acteurs, climat organisationnel, silence organisationnel, théorie de la régulation sociale

Abstract

One of the last official assessment reports of "higher education system," explains its failure by "the low participation of actors" and "climate at the university." In this paper, we propose a theoretical analysis to inform the debate on the performance of "higher education system." Thus we propose an analysis of the "organizational climate" mobilizing work on the theory of social regulation (TRS) Jean-Daniel Reynaud, sociological analysis of the concept of "organizational silence" with contributions from Morrison and Milliken, (2000).

Keywords: performance, higher education institutions, stakeholder participation, organizational climate, organizational silence, social regulation theory

Introduction

Depuis le début du XXI^{ème} siècle, l'enseignement supérieur au Marc a fait l'objet de réformes continues qui ont impactées son « mode de gouvernance », « le statut du personnel », « l'architecture des formations » et « les contenus des enseignements », ces réformes sont régies par les textes de la Loi 01 - 00 portants sur l'organisation du secteur de l'enseignement supérieur et par les orientations de la Charte Nationale d'Education et de Formation. Si l'objectif déclaré de ces réformes est l'amélioration de la qualité de l'enseignement et de la recherche, la performance des établissements universitaires marocains a encore fait depuis, l'objet de multiples rapports alarmants et des prises de positions critiques, voir négatives de la part d'instances nationales et internationales[1].

[1] On peut citer comme rapport d'instances internationales:

Dans cette perspective, publié en décembre 2014, le rapport du Conseil Supérieur de l'Education, de la Formation et de la Recherche Scientifique[2] sur la mise en œuvre de la charte nationale d'éducation et de formation pour la période 2000-2013, a évoqué entre autres, en quelques lignes, deux facteurs explicatifs de la défaillance du système d'enseignement supérieur « la faible participation des acteurs » et le «climat des études à l'école et à l'université ». Ce rapport succède déjà à un autre rapport publié en 2008 [3]et qui a souligné la défaillance de la gouvernance, et l'utilisation déficiente des ressources avec une faible implication des enseignants.

A partir de ces constats, le but premier de cet article est celui de clarifier le débat sur «la participation des acteurs », qui se situent à différents niveaux, internes ou externes aux établissements universitaires et qui interagissent loin de la logique de la bureaucratie Wébérienne. Cette dernière postule que l'efficacité repose essentiellement sur l'effort de rationalisation réalisé par le seul encadrement. Ainsi nous posons la question de recherche suivante : quelles sont les origines de la «la faible participation des acteurs », en postulant que « le silence organisationnel » constitue une manifestation de « la faible participation des acteurs » dans les universités. A ce titre, dans notre analyse on tiendra pour essentielle l'affirmation suivante : l'évolution du système universitaire est un processus complexe mue par des interactions entre l'organisation et son environnement, qui se définit comme une co-évolution (Lewin et Volderba, 1999, McKelvey, 2002) et que le processus interne d'adaptation est un processus social dialectique, qui captive tous les niveaux de l'organisation, définie « la participation des acteurs » et forme le« climat organisationnel ». Aussi nous proposons une analyse du « climat organisationnel » en mobilisant des travaux sur la théorie de la régulation sociale (TRS) de Jean-Daniel Reynaud, et l'analyse sociologique de la notion de « silence organisationnel » avec les contributions de Morrison et Milliken, (2000).

Cet article est agencé en trois temps. Après avoir présenté le contexte des réformes du système d'enseignement supérieur au Maroc[4] et la nature complexe des établissements universitaires (partie 1), nous allons mettre l'accent sur la notion de **Régulation** et celle de **silence organisationnel** (partie 2). La troisième et dernière partie de cet article discute une série de questionnements concernant le climat organisationnel et la justice organisationnelle dans les établissements de l'enseignement supérieur.

1. Réforme de l'université au Maroc

1.1. Contexte général

Les dernières décennies sont marquées par des mutations importantes dans l'environnement des universités, cet environnement est de plus en plus complexe, hétérogène, hostile et surtout moins généreux et incertain. Ce nouvel environnement remet partiellement en cause le devenir des missions traditionnelles d'enseignement, de recherche et de services à la collectivité. Cette évolution a favorisé des débats qui ont gravité autour de trois thèmes : la gouvernance, l'éthique et la performance.

[2] « Le Conseil Supérieur de l'Education, de la Formation et de la Recherche Scientifique est créé en application de l'article 168 de la Constitution et organisé par la **Loi 105.12** du 16 mai 2014. Il remplace le Conseil Supérieur de l'Enseignement [tel qu'il a été réorganisé en 2006 par le Dahir n°1-05-152]. Instance consultative indépendante de bonne gouvernance, de développement durable et de démocratie participative, le Conseil a pour vocation de servir de creuset à la réflexion stratégique sur les questions de l'éducation, de la formation et de la recherche scientifique et d'espace pluriel de débat et de coordination sur toutes les questions intéressant l'éducation, la formation et la recherche scientifique. ».

[3] Royaume du Maroc, Rapport du conseil d'enseignement supérieur (2008). – état et perspectives du système d'éducation et de formation, Rapport analytique, volumes 1, 2, 3 et 4.

[4] Nous proposons une lecture « «managerielle » loin des lectures factuelles axées sur l'exposé chronologique du processus des reformes.

Au Maroc, à partir de 1997, l'université a été dotée d'un dispositif juridique allant vers plus d'autonomie. A ce titre, nombreux sont les travaux de recherche qui ont exposé et analysé le dispositif de réformes, certaines recherches ont privilégié l'analyse chronologiques des processus long et imparfait des reformes [5] ; d'autres recherches ont exploré la mise en place des différents dispositifs de gestion[6] en arguant le plus souvent, de manière implicite et quelque fois explicite que le statut actuel de l'université marocaine, « Etablissement Public jouissant de la personnalité morale et de l'autonomie administrative, financière et pédagogique » pourrait suffire à régler la grande question de la performance du système d'enseignement supérieur.

A contre courant de ces dernières analyses, les premières évaluations des résultats de la réforme ont été alarmantes voir décevantes. Dans ce sens, un des derniers rapport sur l'enseignement supérieur au Maroc , publié en décembre 2014 par le Conseil Supérieur de l'Education, de la Formation et de la recherche Scientifique[7] sur la mise en œuvre de la charte nationale d'éducation et de formation pour la période 2000-2013, annonce page 144 :

1. *« Les enquêtes auprès des enseignants et des responsables de la gouvernance montrent qu'ils ne remettent pas en cause le bien-fondé de la réforme, ni la qualité des recommandations de la Charte. En revanche, ils stigmatisent les conditions dans lesquelles sa mise en œuvre a eu lieu et la manière par laquelle les acteurs ont structuré leur action, organisé le système et communiqué à propos des objectifs de la réforme ».*

2. *« L'insatisfaction est généralisée puisqu'elle ne se limite pas aux enseignants mais s'étend aux autres responsables. Pourquoi ? La raison est que les réformes sont vécues comme des directives subies et non comme des projets auxquels ils ont contribué. Il est évident que les acteurs ne se sont pas appropriés les réformes ».*

3. *« La compréhension de la mise en œuvre de la Charte est le produit d'une époque où des réformes par le haut faisaient partie du mode de gouvernance prédominant. Actuellement, après la Constitution de 2011 et l'évolution de la société, la gouvernance impose la participation des acteurs et des parties prenantes dans le processus de changement afin de permettre à l'université de réaliser un saut qualitatif ».*

Les termes de ce rapport constituent un progrès notable dans la littérature gouvernementale. Toutefois, le consensus sur le diagnostic et l'énoncé des rationalités ne font plus débat, la performance est le résultat des rationnements et des régulations dans des organisations complexes que sont les universités. Aujourd'hui, d'autres lectures sont possibles en postulant le paradigme de la complexité des organisations universitaires.

1.2. Complexité de l'Université.

Les organisations universitaires se caractérisent par leur extrême complexité qui se constate au niveau théorique, institutionnel et organisationnel.
Théoriquement, les universités sont considérées comme des bureaucraties professionnelles (Mintzberg, 1990), d'anarchies organisées (Cohen, March & Olsen, 1972) ou de couplage souple 3 (Weick, 1976). Les universités forment des organisations complexes dont les acteurs sont multiples, à différents rangs, avec des objectifs, des valeurs et des cadres de référence changeants et d'origines

[5] On peut citer Lahlou Loubna, « La réforme de l'Université marocaine entre idéal organisationnel et réalité pratiquée» ; Colloque international : Les universités au temps de la mondialisation/globalisation et de la compétition pour « l'excellence » ; Université Paris VIII (11-14 mai 2009)

[6] A titre d'exemple les dispositifs de : Comptabilité, de Contrôle de Gestion ou la Qualité.

[7] « Le Conseil Supérieur de l'Education, de la Formation et de la Recherche Scientifique est crée en application de l'article 168 de la Constitution et organisé par la **Loi 105.12** du 16 mai 2014. Il remplace le Conseil Supérieur de l'Enseignement [tel qu'il a été réorganisé en 2006 par le Dahir n°1-05-152]. Instance consultative indépendante de bonne gouvernance, de développement durable et de démocratie participative, le Conseil a pour vocation de servir de creuset à la réflexion stratégique sur les questions de l'éducation, de la formation et de la recherche scientifique et d'espace pluriel de débat et de coordination sur toutes les questions intéressant l'éducation, la formation et la recherche scientifique. »

endogène et exogène à l'institution. Ces acteurs sont censés combiner leurs actions, échanger l'information et interférer dans des logiques de coopération, de coordination qui n'écartent ni la concurrence ni l'antagonisme ni les contradictions. Les organisations universitaires sont aussi considérées comme des organisations paradoxales[8], l'approche paradoxale de l'organisation permet une lecture singulière de l'organisation et du changement organisationnel.

D'un point de vue institutionnel, l'université peut être représentée de manière physique ou administrative à partir de ces formations, de ces départements, de ces sites, de ces structures d'enseignement et de recherche ou encore des ces dispositifs de recherche. Les liens entre ces représentations de l'organisation universitaire sont eux aussi disparates, allant de relations contractualisées à des coopérations informelles. De plus les liens externes que les universités entretiennent avec son ministère de tutelle créent un niveau de complexité exogène à côté d'une complexité endogène et organisationnelle.

Au niveau organisationnel, l'hétérogénéité, voire l'ambiguïté, dans les finalités et objectifs se traduit par l'utilisation de moyens hétérogènes, qui nécessitent la mise en œuvre de dispositifs multiples, à la fois complexes et co-constructeurs de la performance. En plus, le long processus des réformes qui a débuté avec la promulgation de la loi 01 – 00 n'est pas encore achevé, ce qui met le système universitaire dans une instabilité qui n'a que trop durée.

En pratique le déficit de performance du système universitaire soulève au moins deux séries de questions ; des questions relatives à la performance et la stratégie (la nature de performance recherchée, la nature de la stratégie affichée, l'autonome et la tutelle) et des questions sur l'autonomie et de la responsabilité (la professionnalisation de la gestion, le Leadership et responsabilité des dirigeants, l'individualisation de la gestion des ressources humaines, les rémunérations liées aux performances).

De ce qui précède, une lecture appropriée de la situation de l'université marocaine est à l'ordre du jour, où il s'agit de traiter la question de la performance avec une lecture centrée sur l'hétérogénéité des activités et des intervenants qui caractérisent l'acte de la production universitaire. Des éléments d'analyse peuvent être retrouvés en référence à la théorie de la régulation sociale pour expliquer les comportements des individus et des groupes dans les organisations. En outre « la théorie du silence organisationnel » peut nous permettre de donner un sens au constat sur la faible participation des acteurs.

2. Régulation & silence organisationnel

2.1 . Régulation

La théorie de la régulation sociale considère la règle comme un fait social dans une sociologie de l'action et vise l'analyse des processus de production, d'interprétation et de modification des règles (Reynaud, 1994). Les règles sont le résultat incertain et fluctuant de la rencontre de plusieurs sources de régulation; c'est pourquoi les systèmes sociaux doivent être analysés comme des entités instables et aux frontières mouvantes, entités dont il est plus pertinent de faire l'histoire que la seule étude instantanée (Reynaud, 1995)

J. D. Reynaud (1988) considère la « Régulation » comme la capacité à produire des règles. Règles est employé au sens large et recouvre aussi bien le domaine de la règle juridique à ses différents niveaux (loi, règlement) que de la règle morale, (formelle ou informelle). Raynaud distingue aussi trois grands types de régulation, les « régulations autonomes », produites par les collectifs de base et les « régulations de contrôle », émises par les supérieurs hiérarchiques et/ou les responsables politiques, donc les tenants du pouvoir, et les « régulations conjointes » : systèmes institutionnalisés, coopératifs, et donc relativement stables, de combinaison des deux premiers types de régulation.

[8] D'après Talbot (2003), le paradoxe organisationnel est une contradiction durable, voire permanente, entre des éléments qui apparemment s'excluent l'un l'autre mais coexistent malgré tout.

Cette régulation conjointe est « le produit d'une négociation explicite ou implicite et s'inscrit dans un accord » (Reynaud, 1995, p.249). La régulation conjointe est la résultante d'un processus de négociation entre les tenants de la régulation autonome (subordonnés) et de contrôle (direction). Cependant, « la régulation conjointe est loin de constituer une simple rencontre mécanique entre une régulation de contrôle et une régulation autonome. La régulation conjointe conduit donc à «l'élaboration de super-règles, sans supprimer forcément les oppositions entre les sources de régulation, mais en tenant compte des préoccupations et des intérêts de chacun.» (Bréchet, 2008, p.20) » Clémence Joffre et Thomas Loilier (2012)[9].

Au terme de cette lecture il parait essentiel la nécessité pour les universités de définir par consensus et différemment les termes de leur performance par rapport aux activités de l'enseignement et de la recherche pour éviter le risque de la faible participation des acteurs .A ce titre, nous postulons que le « Silence Organisationnel » constitue une manifestation majeur la faible participation des acteurs.

2.1. Silence organisationnel

Le silence fait l'objet de plusieurs analyses. L'analyse sociologique du concept de silence est riche d'enseignements, elle retrouve amplement de l'importance dans le contexte des établissements d'enseignement supérieur, elle n'est pas unique.

En effet, en se plaçant dans une vision communicationnelle naïve on pourrait penser que le silence synonyme de l'arrêt de la transmission plus qu'un jaillissement intérieur(Le Breton, 1997). De manière plus subtile, les travaux de Jensen (1973), Hasegawa et Gudykunst (1998), Ephratt, (2008), en sociolinguistique on montre que le silence n'est pas simplement l'absence de sonorité ou de communication, néanmoins il forme un élément essentiel de la communication. Ainsi pour David Le Breton (1997) «il n'y a pas de parole sans silence ».

L'analyse sociologique consacre le concept du silence comme un vide communicationnel et interactionnel apparent. Comme objet de recherches, la nature particulière du concept « le silence dans les organisations » pose de difficultés aux chercheurs au niveau conceptuel et méthodologique (Van Dyne, Ang et Botero, 2003). Néanmoins, le recueil de publications de ce « programme de recherche » comprend certains classiques de la sociologie des organisations (Michel Crozier,1964) et surtout des publications (Morrison et Milliken (2000), Pinder et Harlos (2001), Milliken, Morrison et Hewlin (2003), Craig Pinder et Karen Harlos (2001),Van Dyne, Ang et Botero (2003), Morrison et Rothman (2009), Maria Vakola et Dimitris Bouradas (2005),Tangirala et Ramanujan (2008), qui ont depuis ouvert un champ de recherche sur le comportement organisationnel et qui ont aussi remis à jour les travaux de Albert Hirschman (1970), Hellriegel et Slocum (1974), James et Jones (1974), Woodman et King, (1978).

De ces travaux d'analyse sociologique, le silence est consacré comme un fait social. Cette analyse part du constat que quiconque a eu la possibilité de se trouver face à des conditions où il y ait un décalage entre ce qu'il admet dans son intimité et ce qu'il peut reconnaitre en présence d'autres personnes. Cette situation d'apparent paradoxe, est présentée en analyse sociologique comme un fait social à expliquer par rapport aux normes sociales qui régentent nos interactions quotidiennes (Durkheim (1963), Eviatar Zerubavel 2006). Ainsi arrêté, le silence est régulé par des contraintes sociales qui déterminent le comportement individuel. C'est aussi une démarche communicationnelle individuelle réfléchie qui permettrait à l'individu de réaliser des objectifs propres dans l'interaction sociale. Dans cette perspective, le silence peut avoir plusieurs significations tributaires du sens que d'autres donnent à cet acte.

[9] Clémence Joffre et Thomas Loilier, « L'adaptation vue comme un processus de régulation. Le rôle et la dynamique de la règle dans une organisation du secteur social et médico-social français », Management international / International Management / Gestión Internacional, vol. 16, n° 2, 2012, p. 39-5

Au rang individuel, Craig Pinder et Karen Harlos (2001) expliquent «le silence du subordonné, comme le choix intentionnel de ne pas communiquer des informations critiques sur l'organisation dont on fait partie à d'autres membres en mesure de changer ou redresser ces aspects». A ce niveau on peut distinguer trois motivations du silence individuel dans une organisation, le silence de la résignation, le silence défensif et le silence pro-actif.
Si le silence pro-actif est un choix affranchi de ne pas dévoiler des informations dans un but généreux et désintéressé, le fait de ne pas propager ou de cacher des informations sur l'organisation à l'extérieur de celle-ci sur la négligence ou la défaillance du collègue ou du supérieur permet de créer ou de renforcer l'attache sociale avec les autres. En général, le silence pro-actif peut avoir des effets positifs sur l'organisation, on ne peut pas dire autant pour les deux autres motivations du silence individuel.
Ainsi, en situation de silence de la résignation ou de silence acquiescent, le silence est le produit de la résignation, l'individu - acteur à travers l'expression de ses idées et de ses connaissances se perçoit de son incapacité d'influencer et d'agir dans l'organisation. Enfin, le silence défensif est motivé par la crainte d'un individu qui tente d'éviter de s'exposer aux vindictes des autres collègues ou des supérieurs hiérarchiques (Morrison et Milliken, 2000).

Au niveau collectif, « le silence organisationnel est un phénomène collectif dans lequel le choix dominant à l'intérieur de beaucoup d'organisations pour les employés, est celui de garder pour eux leurs opinions et préoccupations par rapport aux problèmes organisationnels » Morrison et Milliken (2000). Ce type de silence peut être soit la résultante des préjugés des cadres supérieurs soit la conséquence « d'un choix délibéré avec le but de défendre ses propres intérêts, des intérêts qui se trouvent diamétralement opposés à ceux de leurs subordonnés » Jimmy Donaghey, Niall Cullinane, Tony Dundon et Adrian Wilkinson (2011).
En résumé, le silence organisationnel est un acte social, manifeste du « climat organisationnel » qui interagit avec ce climat en fonction de la perception des individus et des groupes de « la justice organisationnelle ».

3. « Climat organisationnel » et « Justice organisationnelle »

3.1. *« Climat organisationnel »*

Il n'existe pas de définition univoque et consensuelle du concept de « climat organisationnel » dont le sens a évolué au cours des recherches. Globalement, la définition du climat change par rapport aux dimensions jugées importantes pour créer le climat (Anderson, 1982). Pour Cornell (1955: voir Thomas, 1976), le climat organisationnel renvoie « aux perceptions qu'ont les individus de leur emploi ou de leurs rôles en relation avec les autres et les rôles tenus par les autres dans l'organisation ». Selon Katz et Khan (1966: voir Thomas, 1976), le climat organisationnel découle de plusieurs facteurs (normes, valeurs, luttes internes et externes, communication, autorité) propres à l'environnement de l'organisation. Enfin, le climat organisationnel, est défini comme «un ensemble de perceptions partagées par les employés concernant les événements, les pratiques et les procédures qui se déroulent à l'intérieur de leur organisation » (Patterson et al., 2005).

En résumé, le climat organisationnel est « un concept global qui peut être considéré comme un déterminant du comportement puisqu'il agit sur les attitudes et les attentes qui ont une influence directe sur les comportements » (Brunet & Savoie (1999), Lewin (1951), Rousseau (1988), Schneider (1975), Taguiri & Litwin (1968)). Le climat, dans les organisations, renvoie à la perception que les individus ont de leur environnement de travail (Parker et al., 2003) et peut ainsi être saisi par une mesure perceptive d'attributs organisationnels que les individus d'un groupe partagent au travers de leurs interactions (Rousseau (1988), James & Jones (1974), Parker et al., (2003)).

3.2. « Justice organisationnelle »

Le concept de justice organisationnelle est crucial dans l'analyse du climat de silence d'une organisation. Cependant ce concept est une construction qui ne peut être défini de manière objective, « sa définition familière dépend fortement du système social ou philosophique dans lequel on se

situe » (Jason Colquitt, Donald Conlon, Michael Wesson, Christopher Porter et Yee Ng (2001)). Selon Soufyane Frimousse et al. (2008) « La justice représente un élément clé de la compréhension des comportements des individus dans l'organisation. Les individus réagissent à partir de leurs perceptions. Pour anticiper, comprendre et modifier leurs réactions, il convient donc de saisir les éléments contribuant à leurs perceptions de la justice».

Cropanzano et al. (2001) présentent une taxonomie des théories de la justice organisationnelle : « Les individus forment leur perception de la justice : soit en comparant leur contribution à leur rétribution (justice distributive : théorie de l'équité), soit en évaluant les procédures qui ont conduit à l'attribution des résultats (justice procédurale : théorie de connaissance du référent) ou encore en évaluant la qualité des traitements interpersonnels (justice interactionnelle) ».

A ce niveau, il convient de rapprocher la logique de cette taxonomie à la réalité perçue par les personnels des établissements de l'enseignement supérieur de différentes catégories et de différents niveaux, pour ceux, nous empruntons à Annabelle Hulin, Typhaine Lebègue & Stéphane Renaud (2015) [10] et à Soufyane Frimousse et al. (2008)[11] les définitions qui suivent, pour se poser une série de questions relative au climat de justice :

La justice distributive

« La dimension distributive repose sur une évaluation de l'équité perçue qui peut être décrite comme un jugement en deux étapes : dans la première étape l'individu compare ses contributions à ses avantages obtenus ce qui est désigné par équité; dans la deuxième étape l'individu compare le ratio d'équité interne au regard des expériences passées et/ou des solutions proposées par d'autres organisations (équité externe) »

Annabelle Hulin, Typhaine Lebègue & Stéphane Renaud (2015)

En terme générique, le principe de justice distributive impose deux grandes questions :

- ***Comment est perçue l'équité interne par le personnel, administratif, enseignant-chercheur ?***
- ***Comment est perçue l'équité interne par le personnel, administratif, enseignant-chercheur, en comparaison avec les autres corps de métiers dans l'administration publique?***

La justice procédurale

« Pour Folger (1996), elle correspond à l'aptitude présumée des procédures à transformer les contributions personnelles en rétributions. Selon Leventhal (1980), la justice procédurale renvoie à la perception par un individu de la justice des composants procéduraux du système social qui règle le processus d'allocation des ressources. Selon Leventhal (1980) « Chaque individu dispose d'un modèle cognitif sous forme de représentations internes de son environnement social qui comporte des composants procéduraux. Il évalue ces éléments structuraux à partir de règles procédurales justes en identifie six : (1) l'uniformité, (2) la suppression du parti pris, (3) la précision de l'information, (4) la possibilité de révision, (5) la représentativité, (6) les principes moraux et éthiques.»

Soufyane Frimousse et al. (2008)

[10] Annabelle Hulin, Typhaine Lebègue & Stéphane Renaud, « L'impact de la justice procédurale et de la justice distributive sur l'intention de rester : Étude différenciée selon le sexe chez les talents ». 33ème Université de Printemps Montréal (Québec) Canada 2015.

[11] Soufyane Frimousse et al., « La diversité des formes de performance au travail : le rôle de la justice organisationnelle », Management & Avenir2008/4 (n° 18), p. 117-132.DOI 10.3917/mav.018.0117

En terme générique, les six principes de la justice procédurale imposent au moins six grandes questions :

1. ***Existe- t- il une uniformité dans l'application des procédures d'allocation, à travers les personnes et dans le temps ?***
2. ***Quel rôle joue le parti pris dans les procédures d'allocation des ressources ?***
3. ***Quelle est la qualité du système d'information et de l'accès à l'information ?***
4. ***Quelle est la réalité de la possibilité de révision ?***
5. ***Quelle est la réalité de la représentativité ?***
6. ***Quels principes moraux et éthiques sont portés et défendus au sein des Etablissements d'Enseignement Supérieur?***

Au delà de toute subjectivité, la vérification de chacun de ces principes peut faire partie d'un programme de recherche empirique[12], néanmoins, les quelques analyses théoriques permettent de jeter un premier éclairage sur le caractère spécifique des établissements d'enseignement supérieur.

Conclusion

En conclusion, si pour J. D. Reynaud (1989) « le système que personne n'a construit est assez solide pour être difficile à réformer», seule une régulation conjointe efficace, est efficace pour gravir la performance toujours recherchée, là encore le jeu des acteurs à tous les niveaux est tenu à s'harmoniser. Ce n'est pas impossible si dans les établissements porteurs et créateurs du savoir, que sont les universités, désirent et œuvrent pour au moins mériter leur qualificatifs et devenir des organisations apprenantes. Il n'est plus tolérable d'accepter la succession des échecs porteur de vulnérabilité et de pléistocratie, où la préoccupation majeure des responsables à tous les niveaux se réduit à la gestion des contestations. La tâche est ardue mais le projet est réalisable.

Abstract

In this paper we will present a complex information system designed for the cadastral database, which will be used by the Rent Department. The classes used in this system are: Property, Construction, Parts of the Building, Floor, Room, Rental Units and Rental Contract. The main objectives are the following: up-to-date record of the cadastral area of buildings on the city's territorial; renting of various units and their subunits and accounting; updating the condition of buildings. To achieve these objectives we defined the following diagrams: Class Diagrams; Object Diagrams; Use Case Diagrams; Interaction Diagrams; Activities Diagrams and State Diagrams.

Keywords: class diagrams, use case diagrams, detail design, sequence diagram

Introduction

The purpose of the diagrams is to present multiple views of a system; this set of multiple views is called a model. A Unified Modeling Language model of a system is something like a scale model of a building along with an artist's rendition of the building. It's important to note that a Unified Modeling Language model describes what a system is supposed to do [22]. It doesn't tell how to implement the system. Object-orientation is a mindset—a mindset that depends on a few fundamental principles. In this hour you'll learn those principles. You'll find out what makes objects tick and how to use them in analysis and design. In the next hour you'll begin to apply Unified Modeling Language to these principles [22].

Description of use cases for a cadastral system

Object-orientation goes beyond just modeling attributes and behavior because we have to consider other aspects of objects as well. These aspects are called abstraction, inheritance, polymorphism, and encapsulation [22]. Three other important parts of object-orientation are message sending, associations and aggregation. Let's examine each of these concepts. Figure 1 shows the classes identified in conjunction with specific attributes and operations.
In this system the cases used are:

- Registration of land or change the owner of a land (sale and purchase)
- Obtaining construction permits and other authorizations in order to build a building
- Registration of a building based on the related documentation
- The design of a floor/apartment
- Sharing spaces in rent

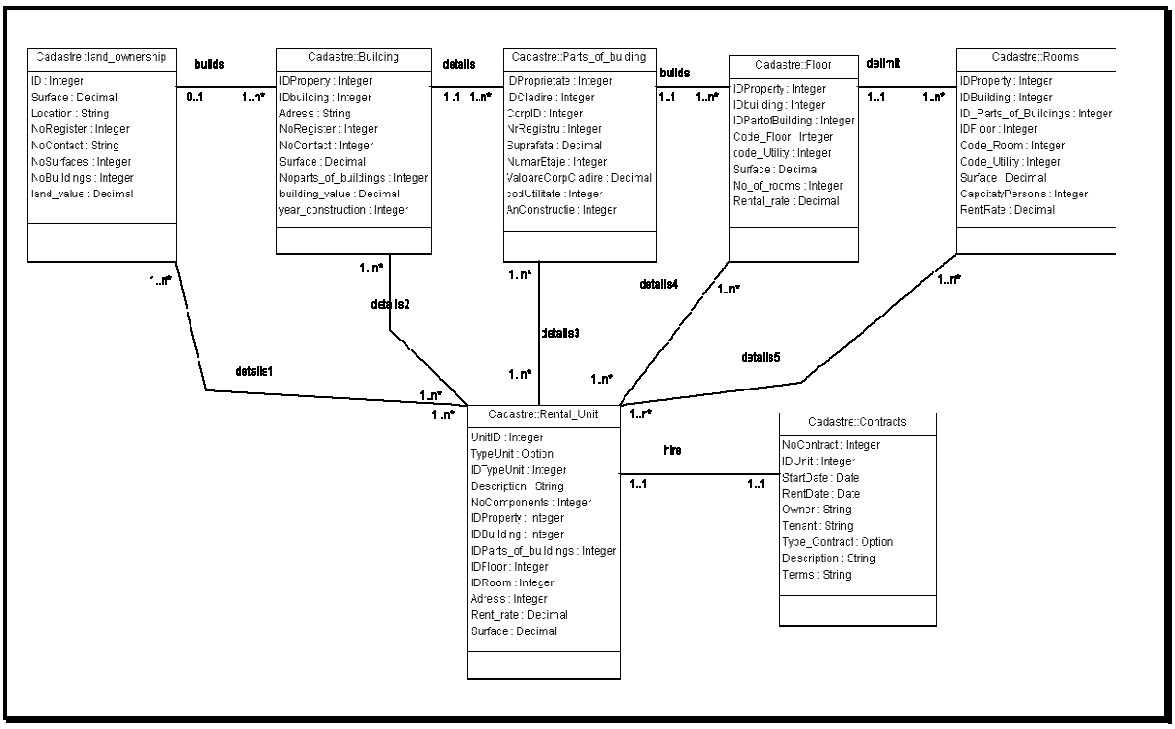

Fig 1. Class Diagram for a Cadastral Database

Drawing up the lease contract (In a rental unit will have a single rental contract). The main actors of the system are:

- The owner - He hires a licensee that lead to good accomplishment and legal boundaries of the owner's request.
- The Hall - Issuing permits and approvals necessary works
- The Cadastral Office - has carried out technical modifications on the building

Amendments (the contract extension or conclusion of the contract) are directly in the lease. Changes relating to the characteristics rent (additional cost, price / square meter ... etc.) are directly in the rental unit. Use cases in summarized form are described in Table 1.

Table 1: Use Cases for a Cadastral System

Use Case	Actor	Description of Use Case
Obtaining construction permits	The Hall	Building permit is obtained from the administrative-territorial unit which has highlighted territory. Data required are the owner, architect and plan situation.
Submitting a building	The Cadastral Office	After completion of work and conduct field verification by a competent authority, the construction can register on the basis of documents which were required to obtain a building permit. On perform verifications in land, building permit must be valid.
Repartitioning a floor / apartment	Licensee at the owner's request	If the owner wants to reconfigure space within a specific floor or an apartment it is necessary to obtain legal advice. After completion of work is required verification of compliance by an authority plan
Sharing space	The Owner	A lease may include several objects (several floors of the same building).

in units of rent		Within this actor are established technical dimensions of rent (price / square meter)
Drafting of the lease	The Owner	In practice a lease is a rental unit in one of subordination. The rental agreement contains data on the customer, the range of billing and other information relating to the payment.

Defining state diagrams

The state diagram refers to identify activities, messages start point and end point depending on the events occurring in that system. Generally a transition capture a state diagram of the event, and is performed on various components of the system. There are some aspects which will define the flexibility of the system hardware:

- The easiness with which the equipments can effect various operations of data input, output, processing and transmission;
- The facilities offered to end-users;
- Equipments performance, as to their utilization;
- Equipments power to integrate- that is their ability to interconnect and interface, thus allowing coordinating and synchronizing when effecting several heterogeneous applications.

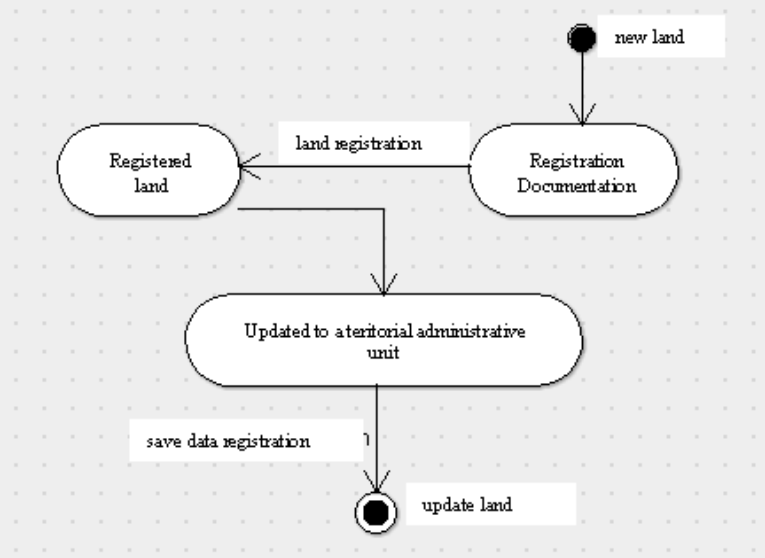

Fig 2. State diagram for the class property

Define interaction diagrams charts activities

Activities Diagrams are used in dynamic use of the system. Include items from left to right and the messages they exchange objects from a starting point that usually derives from use cases. The messages are followed progressively over time.

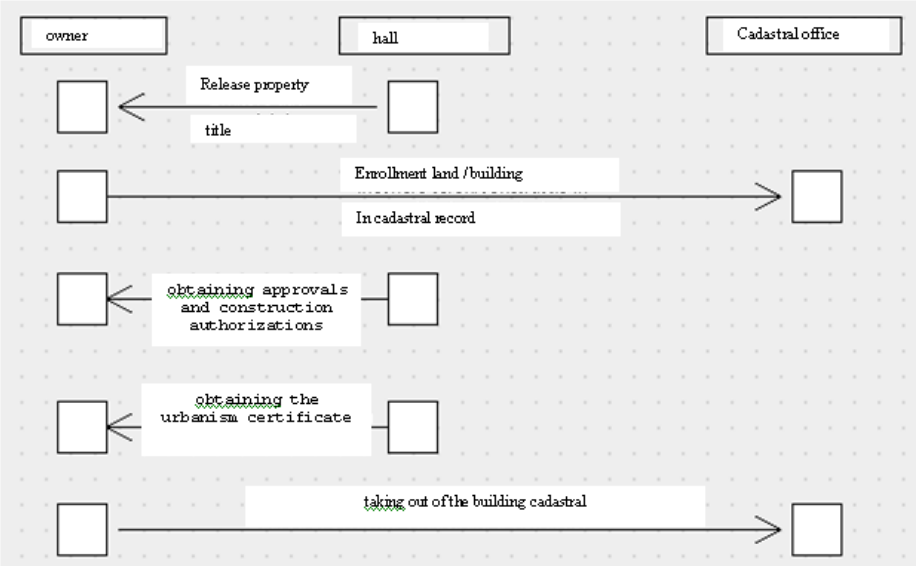

Fig 3. Collaboration Diagram for the registration of land / building

Sequence diagram can be presented and detailed the agenda mentioned messages in collaboration diagrams.

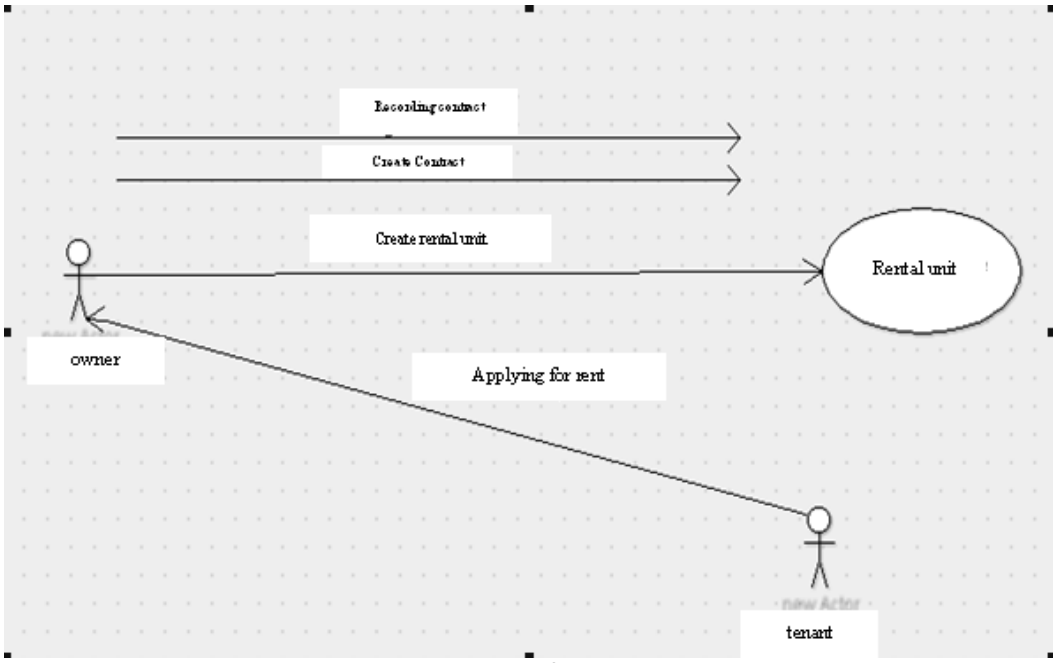

Fig 4. Sequence diagram for recording contract

Figure 5 shows the activity diagram to add contract. Identify actions, it represents the state, the start point and end point.

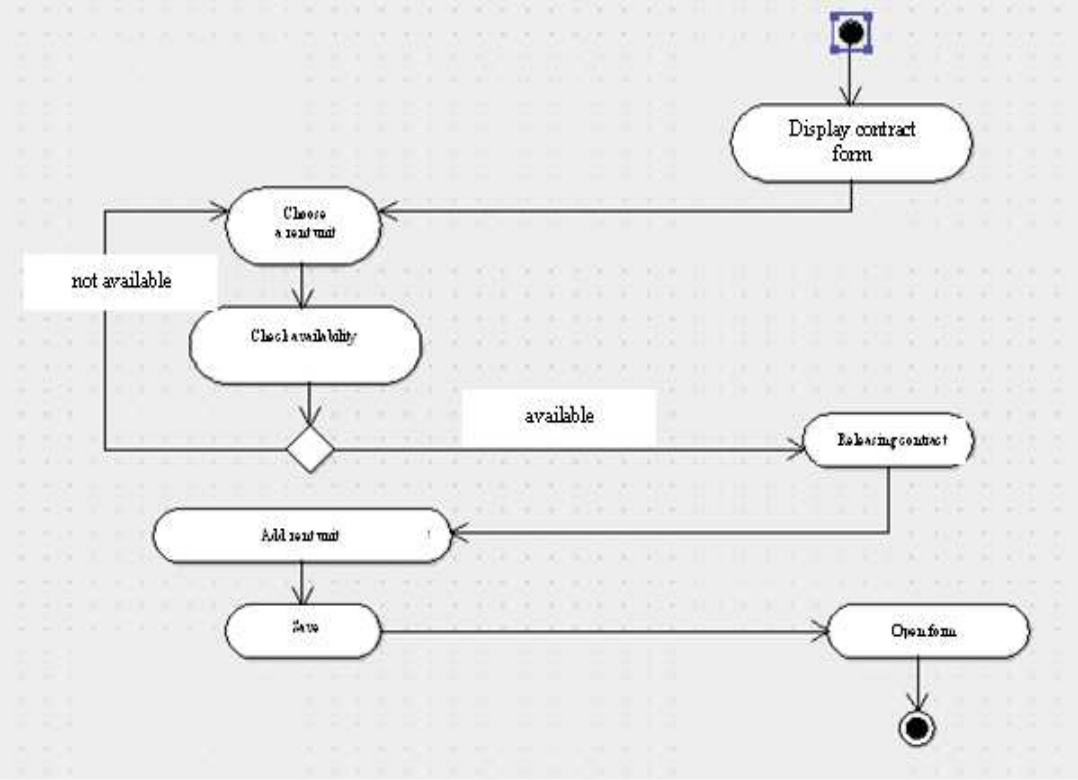

Fig 5. Diagram of activities to add agreement

It is well known that on the home and abroad market an impressive number of methodologies existed, exist and will exist, each of them having both advantages and disadvantages.

The Detail Design of the Information System Components is "real art". The adaptability of the system to the changes that intervene in it and to its maintenance and exploiting facilities depends to a great extent on the way in which each component is conceived and designed [17]. As the matter of designing of the system is a complex problem we will confine to making some suggestions [20]:

a. When designing primary documents as source of integrating data it is desirable that drafts and their video-formats be very close to the real image and at the same time they should be as suggestive and self explanatory regarding their utilization;

b. In the activity of designing outputs the form of presentation (list, table, graph) will be paid attention to as well as to their complexity (synthetic and analytical situations) depending on the category of end users. .

c. In the order to design the code systems of date it will be resorted to:

- Using sequential codes with groups formation, they are the most flexible for the maintenance of the code;
- Mnemonic codes or the descriptive ones are very suggestive in their use;
- The bar codes or RFID (Radio Frequency Identification) offer increased facilities regarding the integration of information systems.

d. When designing the applications programs several aspects will be considered [18]:

- Creating an integrated developing environment with a view to editing the source code, compiling, testing and generating the programming documentation. All these activities can be included in a complex software package which offers a graphic interface which is friendly to the users;
- Based on finite automatons, programs can be generated automatically for designing entities (data collections) and loading data;

- Building and implementing some general drivers of connecting clients to various databases and transforming the entities into Java classes. Such a solution offers the possibility to integrate data in various locations and sources which are managed by different database management systems. In this way data portability within systems is increased.

e. Designing data organization within systems. Any Information System or application operating with a great volume of data appeals to a certain way or another of organizing data. At present there is a multitude of models, methods and techniques of organizing data. There is a tendency to develop OOBD (Object Oriented Data Bases) but the greatest weight is held by applications that use RDB (Relational Data Bases): or non SQL Data Bases. Considering the limited space of this paper we will confine to pointing out some aspects regarding RDB (Relational Data Bases) flexibility.

In most information systems the management of databases is not considered to include neither explicit nor hidden inconsistencies [19]. In real life situation information often come from different contradicting sources.

Software development projects require a lot of "paperwork" in the form of requirements documents, design documents, test plans, schedules, checklists, release notes, etc. It seems that everyone creates the documents from a blank page, from the documents used on their last project, or from one of a handful of high-priced proprietary software engineering template libraries. For those of us who start from a blank page, it can be a lot of work and it is easy to forget important parts.

Bosses and organizations still tend to think that people whom are managed and employed and paid to do a job should do what they're told to do. We are conditioned from an early age to believe that the way to teach and train, and to motivate people towards changing what they do, is to tell them, or persuade them [11]. From our experiences at school we are conditioned to believe that skills, knowledge, and expectations are imposed on or 'put into' people by teachers, and later, by managers and bosses in the workplace.

For many organizations, information and the technology that supports it represent the organization’s most valuable assets. Truly, information and information systems are pervasive throughout organizations – from the user’s platform to local and wide area networks to client servers to mainframe computers. Many organizations recognize the potential benefits that technology can yield. Successful organizations, however, understand and manage the risks associated with implementing new technologies. Thus, management needs to have an appreciation for and a basic understanding of the risks and constraints of IT in order to provide effective direction and adequate controls.

Management has to decide what to invest for security and control in IT and how to balance risk and control investment in an often unpredictable IT environment. While information systems security and control helps manage risks, it does not eliminate them. In addition, the exact level of risk can never be known since there is always some degree of uncertainty. Ultimately, management must decide on the level of risk it is willing to accept. Judging what level can be tolerated when weighted against cost, can be a difficult management decision. Therefore, management clearly needs a framework of generally accepted IT security and control practices to benchmark their existing and planned IT environment:

- Increasing dependence on information and the systems that deliver this information
- Increasing vulnerabilities and a wide spectrum of threats, such as cyber threats and information warfare
- Scale and cost of the current and future investments in information and information systems
- Potential for technologies to dramatically change organizations and business practices, create new opportunities and reduce costs
- Free and open technologies in business;
- Legal aspects.

Conclusions

The control of the planning and organization activities for the I.S. systems means the use of the feedback in order to monitoring the project, including comparing the planned stage with the actual stage of evolution. In addition, the control means making the right decisions in order to accelerate or to reorganize

the activities to be able to finish them in time as well as to motivate the team to do the job right and to be able to remain in the fixed budget.
Once the time and financial resources are dealt with, we must take care of the human resources as well. Mainly this means to communicate with the team's members who have been selected for their competence and abilities. The aims for the project's productivity must be fixed and the members of the team must be motivated to reach the aims.
As an evaluation consequence, we can easily establish the risk exposure as far as the planning and organization activities of the complex I.S. projects are concerned.

The Optimal Sum Insured in Life Insurance

Mgr. Katarína Rentková, PhD., Comenius University in Bratislava, Faculty of Management FM CU, Bratislava, Slovakia, katarina.rentkova@fm.uniba.sk

Mgr. Jan Janać, PhD., Comenius University in Bratislava, Faculty of Management FM CU, Bratislava, Slovakia, jan.janac@fm.uniba.sk

Abstract

An article deals with the issue of optimal sum insured in life insurance. The aim of article is to create formula and to analyze its use in case of calculating the optimum sum insured for protection of family property upon death. The publication focus on the ideal sum insured in case of life insurance. It focuses on describing and comparing elements, which are typical for insurance. Article deals with the actual issue because the life insurance market is still growing market. Reasons for the increase in the life insurance market are different. This may include: the pension reform, increasing people's awareness of the need for the individual security for retirement, increase the standard of living.

Keywords: the life insurance, the optimal sum insured, the ideal sum insured, the case study

Research objective

The main issue of this article is the life insurance, especially we observe the optimal sum insured in life insurance. The general object is life insurance; the problem is to define the optimal sum insured and the ideal sum insured in life insurance. Life insurance is a protection against the loss of income that would result if the insured passed away. The named beneficiary receives the proceeds and is thereby safeguarded from the financial impact of the death of the insured.

„With a 35% share of the global market, the European insurance industry is the largest in the world, followed by North America (29%) and Asia (28%). Insurance makes a major contribution to economic growth and development. It facilitates economic transactions, encourages risk management, promotes financial stability and encourage stable and sustainable savings and pension provision.“ (Insurance Europe)

Objectives, methods and methodology

The research is processed by using a wide scale of the scientific methods and procedures. The specific range of methods was based on the research needs of the individual parts. The intention is to follow the logical continuity of the articles ‘parts, the correctness and the adequacy of information and data. First part is focused on the definition of life insurance and on the determination of the optimal and ideal insured sum. This section is prepared by using the analytical methods – the analysis, the casual analysis, the synthesis, the induction and the deduction. We analyzed scientific publications and scientific articles, papers by various authors (e.g. Crews, T. B. (2009), Fowles, D. (2008), Garman, E. T. – Forgue, R. E. (2012)) and we could determine the calculus of optimal sum insured, by using this base information. The first part is based on preparation and explanation of formula for calculation the optimal sum insured. (Mitková, 2010)

Empirical research was carried out and is based on a case study which deals with using the prepared formulas. This case study is based on practical example. The case study analyzes the optimal sum insured

in the family. The family consists of four members - father (Simon Matlak – employed; he wants secure his family in case of death), mother, two sons - Richard - 5 years and Roman - 7 years. The second part is prepared by using scientific methods – the causal analysis, the mathematical and the statistical methods. The goal of life insurance is to provide a measure of financial security for the family after/if Mr. Simon Matlak die. So, before purchasing a life insurance policy, he should consider his financial situation and the standard of living he wants to maintain for his wife and 2 sons. He needs to pose questions: “who will pay for his funeral costs? Will there be adequate funds for future or ongoing expenses? The research question is: "How to solve the problem of Mr. Simon Matlaks´ family?"

Article represents the basis of the planned long-term research which expected the analysis of insurance market, more exactly we want to focus on the selected states (Slovakia, Serbia) and we want to analyze the life insurance market in these states. The goal is to prepare more case studies and to compare the different situations on those markets.

Introduction

Sellers of life insurance, financial consultants, insurance agents and everybody who is dealing with the life insurance through their work face the same problem: setting the sum insured under multi-risk coverage, especially in the definition of the sum insured, which is used to cover the risk of death. Everything what would be ideal or sufficient for the client, what will cover the loss of income to the family of the client, it is generally too expensive for the client from middle-class. Consultant has the task of finding the best possible combination of premiums and the sum insured. It is important that the client provide for himself and his family a sufficient financial coverage, but for minimum money.

The sum insured represents one the most essential parameter of life insurance for the customer. If the client has very cheap insurance, but the amount of coverage does not cover adequately the risks, it is useless for the client to pay insurance. Correct and optimal insurance coverage constitutes a key factor for quality assurance.

Each client's financial plan has to contain its purpose and has to predict the client's life situation that can change its own requirements. Establishment of the financial plan / financial portfolio consists of several important steps. The first step is to identify the client's objectives. After determining the financial objectives of the client, the second step is to determine the partial objectives. Each financial product (life insurance, too) has its own goal. The aim of life insurance is to ensure income of families and individuals in situations where income is at risk.

The most common cases when there is a risk that the client will lose a part or even the whole of his income are:

- permanent effect of injury;
- severe disease;
- disablement;
- loss of employment;
- death.

All of these risks must be minimized by products in the category securing income. In all of these situations, the stability of a client is imperiled and it is of greatest importance to counteract all risks and then do the next steps in building the client portfolio. It is most common to use insurance to cover these risks but there are other methods which are more effective in certain cases.

In Slovakia it is becoming more and more relevant to secure income through life insurance. (Pawera, 2007) Unlike Germany where the ratio of life versus non-life insurance (expressed by the sum of premiums) 46 to 54, in Slovakia the ratio is 37 to 63. That is why it is most probable that the insurance

sector will expand in the field of life insurance or in the boundaries of securing income. The key determinant of the growth of insurance demand is the growth of the average pension of the population, which is another proof of the rise of overall premiums in life insurance. (Komorník, Janać)

We completely agree that the permanent consequences of accident represents the greatest risk to family income but in this article we are dealing with the setting of the sum insured in case of death of one or both members of the family. The said insurance risk is most often negotiated risk of life insurance and consultants frequently incorrectly determine the amount of its financing that can considerably influences the quality and the amounts of family income and undermine the financial situation of the family.

Lost of income can be solved through the life insurance, even if the loss of income is the result of the loss of employment. Today's insurance policies are very flexible and they allow clients to, except the interruption of payment of insurance premiums, the partial purchase of saved up funds. The client can use it to overcome a certain period when he is unemployed. (Komorník, Janać)

An additional insurance for critical illness is standard risk which is covered through life insurance. The sum insured is arbitrary and the proceeds from the sum insured should be used to finance the treatment of critical illness on the basis of which the sum insured was paid.

1 Monthly rent as a form of ensuring income

There are several possibilities how to ensure family income through life insurance. Financial consultants and agents are governed during the determination of the sum insured mainly by client wishes.

However, the correct way is:
1. Firstly, to make a cash flow analysis of the client.
2. Based on this analysis to define the client's needs in case of loss of income of one or both holders of income to the family.
3. On the basis of identified needs to answer the question: "How much money the family will need in case of loss of income for covering their needs?"

In case that the family has debts, it is important that they should be immediately repaid, because we need to be protected our client (family) prior to payment of the interest to banks from the insured amount. The sum insured will be increased by that amount. (Joehnk – Billingsley – Gitman, 2011)

Monthly rent (R) is the amount that family will need in case that the family lost one or all income. If the client can determine at this risk also time during which he would like to secure a monthly rent for himself and family, then we know to optimize the sum insured. In case of death, it can, for example, be till the children are not adults and they will not be able to earn money. In case of permanent consequences of accident time of receiving annuity is vague and we do not know to optimize the amount of coverage over time limitation of receiving of rent. (Komorník – Majerčáková – Husovská, 2011)

2 The ideal sum insured – long term rent

The following situation has become in practice and serves as a practical example. We have a father who is called Simon Matlák. Father aims to leave rent to his family in case of his death. Amount of € 500 per month should cover the shortfall of income. Financial consultant suggested father to set the amount of coverage the risk of death by the formula:

$$VK = \frac{R}{(i \div 12)}$$

where is:

- VK = sum insured
- R = monthly rent (the amount by which the client will cover a lack of income)
- i = interest rate expressed as a percentage divided by 100

If we calculated that today it is possible to have a 3% annual rate, Simon should be insured for the sum of € 200,000, in the event his death, the family could get amount of EUR 500 as monthly rent. Such sum insured is indeed ideal, but for Simon's family is too expensive. The high sum insured means also high premiums. If Simon has taken out insurance for 30 years, the minimum monthly premiums would be 400 EUR, which the family cannot afford.

Therefore, the question arises: "How to solve this problem of Simons´ family?"

Simon had a goal to ensure his family financially so he decided to provide the sufficient funds while the children are young and until they will be able to earn money themselves. The family consists of two children, Richard - 5 years and Roman - 7 years. We (Simon and financial consultant) want to ensure family revenue in the amount of 500 EUR until the youngest son will be 23 years, so while he will finish his study at the university.

At this point, we have another variable: time of use of rent. Since we already know the time, we can try to calculate the optimal amount of insurance premiums for life insurance. It is important that principal sum and interest together have brought 500 EUR each month. In our case it is a time of 18 years. In other words, if something happened today, the family will receive an annuity of 500 EUR per month for a period of 18 years. This amount will be spending from interest and the principal sum. All resources will be exhausted from life insurance at the end of the period.

3 The optimal sum insured – time-limited rent

The importance of the calculation is to determine the amount of cover in case that money will be levied at the same time from principal investments and also from income arising from interest. We have obtained the formula for calculating the sum insured, wherein the proceeds are invested, as follow:

For the first year, we needed to deduct an annuity from the invested capital (CP) and received interest (i):

$$CP \times (1 + i) - R$$

In the second year we repeated that operation with the fact that interest is calculated only from the balances of last year:

$$(CP \times (1 + i) - R) \times (1 + i) - R$$

Then we adjust formula:

$$CP \times (1 + i)^2 - R \times (1 + i) - R$$

For the third year we have received:

$$CP \times (1 + i)^3 - R \times (1 + i)^2 - R \times (1 + i) - R$$
$$CP \times (1 + i)^3 - R \times ((1 + i)^2 + (1 + i) + 1)$$

If we adjust this formula to an indeterminate number of years, where "n" is the number of years:

$$CP \times \underbrace{(1+i)^n - R \times ((1+i)^{n-1} + (1+i)^{n-2} + \cdots + (1+i) + 1)}$$

We express geometric series as follows:

$$\frac{(1+i)^n - 1}{(1+i) - 1} = \frac{(1+i)^n - 1}{i}$$

We obtain the following formula, which we can customize:

$$CP \times (1+i)^n - R \times \frac{(1+i)^n - 1}{i}$$

We add to the formula residual value (hereinafter referred to as "ZS"). The residual value is the amount of financial funds that the client wants to have after the period of receiving rent. In practice, it is the amount that is most commonly expressed as zero, because the client receives funding as long as he has the sufficient funds on the account.

$$CP \times (1+i)^n - \frac{R}{i} \times (1+i)^n + \frac{R}{i} = ZS$$

$$CP \times (1+i)^n - \frac{R}{i} \times (1+i)^n = ZS - \frac{R}{i}$$

$$(1+i)^n \times (CP - \frac{R}{i}) = ZS - \frac{R}{i}$$

$$(1+i)^n = \frac{ZS - \frac{R}{i}}{CP - \frac{R}{i}}$$

$$(1+i)^n = \frac{ZS \times i - R}{CP \times i - R}$$

Finally, we get a formula that determines the number of years necessary for the client to benefit from its funds under specified interest and annuity needed, and we know the amount invested and the financial balance of the investment account after "n" years:

$$\boldsymbol{n = \frac{\log \frac{ZS \times i - R}{CP \times i - R}}{\log(1+i)}}$$

We can insert variables in the formula that we use to determine the sum insured. The formula will be as follows:

$$\boldsymbol{t = \frac{\log \frac{ZS \times i - R}{PS \times i - R}}{\log(1+i)}}$$

where is the:
PS = sum insured
R = annual rent (the amount by which the client will cover a lack of income)
i = interest rate expressed as a percentage divided by 100
t = time during which the client uses the required rent

ZS = residual value (financial resources remaining in the account at the end of a defined investment period). In practice, this amount often heading to 0.

We can derive also CP, by using the same procedure:

$$CP \times (1+i)^n - R \times \frac{(1+i)^n - 1}{i} = ZS$$

$$CP \times (1+i)^n = ZS + R \times \frac{(1+i)^n - 1}{i}$$

$$CP \times (1+i)^n = ZS + \frac{R}{i} \times (1+i)^n - \frac{R}{i}$$

$$CP = \frac{ZS + \frac{R}{i} \times (1+i)^n - \frac{R}{i}}{(1+i)^n}$$

$$CP = \frac{ZS \times i + R \times (1+i)^n - R}{i \times (1+i)^n}$$

Finally, we get the formula by which we can calculate the required amount of capital, by specified interest, rent and residual value.

$$\boldsymbol{CP = \frac{ZS}{(1+i)^n} + \frac{R}{i} - \frac{R}{i \times (1+i)^n}}$$

If we substitute the variables in the formula - time instead of "n" and the sum insured instead of capital, we get the following formula:

$$\boldsymbol{PS = \frac{ZS}{(1+i)^t} + \frac{R}{i} - \frac{R}{i \times (1+i)^t}}$$

where is the:
PS = sum insured
R = annual rent (the amount by which the client will cover a lack of income)
i = interest rate expressed as a percentage divided by 100
t = time during which the client uses the required rent
ZS = residual value (financial resources remaining in the account at the end of a defined investment period). In practice, this amount often heading to 0.

We can use the formula also the example of the Simon family, where we want to calculate the optimal sum insured in the event of the death of Mr Simon. If the parameters are defined as follows:
ZS = 0
t = 18
R = 500 EUR / m (6000 EUR / year)
i = 3% (interest, which can be obtained on the market)
We receive calculation, which significantly reduces the sum insured and also insurance.

$$PS = \frac{ZS}{(1+i)^t} + \frac{R}{i} - \frac{R}{i \times (1+i)^t}$$

$$PS = \frac{0}{(1+0{,}03)^{18}} + \frac{6000}{0{,}03} - \frac{6000}{0{,}03 \times (1+0{,}03)^{18}}$$

$$PS = 0 + 200.000 - 117.647$$

$$\boldsymbol{PS = 82.353\ EUR}$$

Using the formula, we get the sum insured which is the amount of € 82,353. That amount is less than half the ideal sum insured. In case of optimal sum insured, the family is covered by the amount of 500 EUR every month for 18 years. If the family had any debts and they would like to repay these debts as soon as possible, because their income is at risk, this amount must be added to an optimal level of cover. Also, if the family wants to leave certain amount of their descendants after the expiry of rent, ZS cannot be 0 in the formula but we need to replace 0 by using the desired financial value. (Janać, 2010)

If we deal with life insurance only as the cover for risk of death, without saving components, then it would be necessary to change the sum insured every year, according to the client's needs. For example, in our case of Simons´ family, it is important to reduced sum insured in the following year, because the time of for economized the rent is minus one year. The sum insured, in this case, would be € 80,000.

Conclusion

In practice, such changes of the financial portfolio and of insurance contracts are not frequent. The main reason is a combined life insurance, which involve also a saving component and they do not allow high frequency changes in sum insured. Even this is not efficient, because if we diminished the sum insured, the client should less saved up funds. In that case, we would endanger his retirement financial plan. The second reason is the client's age and the fact that the premium to cover the risk of death is each year more expensive and it is questionable whether we would save on premiums if we edited every year sum insured downwards.

Organisational Culture and the Use of Knowledge-Based Engineering Systems in Saudi Industrial Firms

Authors: Mujid Attar & Dr.Kyeong Kang , Affiliation: University of Technology Sydney, City: Sydney , Email: Majd.Attar@gmail.com ; 99151298@student.uts.edu.au

Abstract

The main aim of this study to investigate what is required to achieve in the effective use of knowledge management system, such as: knowledge assets, knowledge sharing, learning, leadership, and the use of technologies. In order to benefit from these main pillars of knowledge management we need to identify each one and understand its main use in the evaluation of the knowledge based engineering system in Saudi context. In order to succeed it, the organisation and its key compensations are the most distinguished drivers of knowledge management. The main determination is to cultivate a conceptual model, which comprehends the influence of organisational culture on the main pillars of knowledge management towards the effective use of knowledge based engineering system in Saudi industrial firms.

1 Introduction

Today, economies are gradually created on knowledge, which is now known in Saudi firms, growing into a knowledge-based economy, which offers an emphasis on the role of information, technology and learning in economic performance. The Kingdom of Saudi Arabia is widely known with its unique culture and heritage, which has been preserved since the inception of the culture (Eid 2011). The cultural setting of Saudis is actually an Arab and Muslim culture. Today, Saudi Arabia visitors are subjected to the same rigorous Islamic law as Saudis. In this regard, different enterprises in Saudi Arabia are being subjected to a greater extent influenced by the cultural aspects of the Islamic community. Hiring employees in a local enterprise consider a clear stipulation that employees, whether of Saudi origin or otherwise, must be governed by similar policies and follow comparable requirements for their enterprises. That must be subjective by Saudis religion law, which is Islam. Where Islam plays a vital role in persuading the business community in Saudi Arabia.

The significance of the organisation culture is increasingly essential for managers to understand the Saudi context, which is often problematic (Al-Adaileh and Al-Atawi 2011, Eid and Nuhu 2011, Adlan and ten Have 2012). In addition, information systems are increasingly imperative for the organisation (MacDonald 1996, Liu 2003, Liu, Dai et al. 2007). Organisation's around the world have been able to gain a substantial amount of independence, due to the information systems that can transport a competitive advantage for the organisation. An organisation needs to be grounded in a way that can continually grow and increase their efficiency and effectiveness; they need to ensure the most robust system in place, which can ensure the long-term survival of the competitiveness of the organisation. Today,

information systems have become a fundamental enhancement for storing employee's information as well as other aspects of the company. The utilization of information systems has completely transformed the performance of responsibilities within the work environment into a digital manner (Alhaqbani 2013).

The purpose of this study is to examine the influence of organisational culture on the main pillars of knowledge management towards the effective use of knowledge-based engineering system in Saudi firms. In particular, the research question is:What are the main factors that influence the use of knowledge-based engineering systems in Saudi firms?

2 Literature Review and Theoretical Background

This section describes the related studies to provide a foundation for developing a conceptual model.

2.1 Organisational Culture

Culture is represented everywhere in the surrounding of an organisation, that is created by interactions with people and shaped by leadership behavior, and set of structures, practices, rules and norms that guide and constrain behavior to a certain direction. Culture exists in different levels, which is created and manipulated to form small level of teams or group members or to a big level such as nations. Culture is also a significant element that grows an energetic organisation (Schein, 2010).
A number of scholars have developed integrative frameworks of organisational culture; since culture is a complex phenomenon ranging from underlying beliefs and assumptions to visible structures and practices, dynamic doubt also exists as to whether organisational culture can actually be "measured" in a comparative sense (Denison, D., Haaland, S. & Goelzer, P., 2004,p.99). Thus "organisational cultures, like other cultures, develop as groups of people struggle to make sense of and cope with their worlds" (Trice and Beyer, 1993, p.4).

How then we should think about the "essence" of culture and how should we formally define it? The most useful way to arrive at a definition of something as abstract as culture is to think in dynamic evolutionary terms. If we can understand where culture comes from and how it evolves, then we can grasp something that is abstract; that exists in a group's unconscious, yet that has powerful influences on group's behavior.

However, culture is hard to define, it is an abstraction. Each person may have his or her own understanding of culture. There are hundreds origin of culture, each of them is point of view, an outlook. (Aliferuke and Bodewyn's, 1970:54) A study of hundreds definitions of culture by Kroeber, Kluckhohn, & Untereiner (1952) even shown that there are 164 meaning of culture and the definition of culture has changed over times. There is no fixed, universal definition or understanding for culture, and neither for organisational culture, there is no single definition for it. In

general, Culture has been defined in many ways, according to Kluckhohn (1951a: 86, 5) quotes as a consensus of anthropological definitions; "Culture covers patterned ways of thinking, feeling and responding, acquired and conveyed mainly by symbols, establishing the characteristic achievements of human groups, including their expressions in artifacts the critical core of culture consists of traditional (i.e. historically derived and selected) ideas and particularly their attached values". In the other hand, Kroeber and Parsons (1958;583) arrive at a cross-disciplinary definition of culture as "conveyed and created content and outlines of values, ideas, and other representative meaningful systems as features in determining of human behavior and the artifacts formed through behavior." Triandis (1972;4) differentiates "subjective" culture from its appearance in "objective: artifacts and defines the former as "a cultural groups features way of perceiving the man-made part of its environments." Culture, in this sense, includes organizations of values; and values are among the construction of culture.

Culture is to human collectivity what personality is to an individual. Personality has been defined by Guilford (1059) as "the collaborating cumulative of personal characteristics that affect the individual's response to the environment." Culture could be defined as the communicating combination of common characteristics that influence a human group's reaction to its environment. Culture determines the individuality of a human group in the same way as personality regulates the identity of an individual. Moreover, the two interact; "culture and personality" use a classic name for psychological anthropology (Bohannan, 1969: 3; Barniuw, 19973). Cultural traits sometimes can be measured by personality tests (Hofstede, G., 1980,p.25,26).

According to Hofstede definition of culture as a combined encoding of the human mind, the word is kept for relating entire societies; for groups within societies, "subculture" is also used. And how culture outlines are ingrained in value organizations of major groups of the population and how they are stabilized over long stages in history (Hofstede, G., 1980,p.13) (Hofstede 1980). Moreover, culture includes the acquaintance that people need to have in order to utilize effectively in a social setting. Much of culture is reproduced in the products of the mind, such as language, myth, art, kinship, norms, values, and shared meanings about social behavior (Keesing, 1981). Some fundamentals of culture are objective (e.g. tools) and some are subjective (e.g., beliefs, attitudes) according to (Gannon, M. & Newman, K., 2002) main definitions.

In the other hand, Schein has defined organisational culture as a characterized attitudes, beliefs, experiences, and values of people in a given organisation. Organisational culture has long been emphasized as vital for organisation performance, organisation development, and human resource development (Barney, 1986a; Egan et al.,2004). Schein (1985) also emphasized organisational culture as: the deepest level of basic assumptions and beliefs that are shared by members of an organisation, that operate unconsciously, and that define in a basic "taken-for-granted" fashion an organisation's view of it and its environment. These

assumptions are learned responses to a group's problems of survival in its external environment and its problems of internal integration [p.6] (Egan, 2008, p.301-302).

In result, Hofstede's main definition of culture is considered a high relevance for many researchers on the emphasis of culture and its effect of human mind programming towards groups within societies; where culture patterns are origin from value systems of groups within the population of similar societies. However, Schein has focused more on the definition of organisational culture in which it holds certain characteristics of attitudes, beliefs, experiences, and values of people in a given organisation.

Therefore, the role of both culture and organisational culture depends highly on the behavior background of people who are the main members of the society. Behavior influence and generates a competitive advantage for employee's performance within the organisation. First, a strong culture within any organisation helps group members to understand problems, evaluate the situation, share values and unite people to behave and in the correct and proper manner. Secondly, identifying the problem and evaluating a suitable solution will help narrow down the decision making process. Third, a strong culture will develop a decent relationship among members of the group; improve the working environment to be successful within the organisation.

2.2 Types of Culture

2.2.1 **Vertical & Horizontal Cultures**

According to Triandis, cultures are defined in both: vertical cultures which accept hierarchy as a given; people are different from each other. Hierarchy is a nature state were whoever is on the top "naturally" had further power and privilege than those of the bottom of the hierarchy. In the other hand, horizontal cultures accept equality as a given and people are essentially alike, and if one is to split any resource it should be done equally (Triandis, 1980, p.18-19).

One of the basic qualities of cultures differentiation is the way people sample information of a particular type, the behavior that is suitable for the information gets to be involuntary, so that people don't have to think how they are hypothetically to behave (Triandis, 1980, p.20). Perhaps the most motivating feature about culture is that basic expectations are not interrogated; they influence thinking, emotions, and actions deprived of people noticing that they do (Triandis, 1995).

Vertical relations are most shared in societies that are high in (Hofstede's,1980a) power distance, however horizontal relations are most common in societies that are low in power distance. The vital point is that vertical or horizontal, collectivist or individualist's cognitions become noticeable depending on the situation. Also, there is a tendency for the vertical collectivist and horizontal individualist cultures to be more abundant than the other two forms.

2.2.2 **Individualism & Collectivism**

The custom dominant in a given society as to the degree of individualism/collectivism expected from its members will strongly affect the nature of the relationship between a person and the organisation to which he or she belongs. More organisations; in a society in equilibrium, the organizations should in return assume a broad accountability for their members. Whenever organisations terminate to do that as in the emerging capitalism in nineteenth-century Europe, and today in many less-developed countries there is conflict between people's values and the social order, this will lead to either a change in values toward more individualism, or force toward a different, more collectivist social order (such as state socialism), or both (Hofstede, G., 1980,p.217).

The level of individualism/collectivism in a society will affect the organisation's members' motives for obeying with organisational requirements. Following the terminology presented by Etzioni (1975), we can undertake more "moral" involvement with the organisation where collectivist values overcome and more "calculative" involvement where individualist values succeed. Etzioni discriminates between "pure" and "social" more involvement' "Pure" more involvement tends to develop in vertical relationships, such as those between teachers and students, priests and parishioners, leads and followers. 'Social' participation tends to mature a horizontal relationship like those various types of primary groups. Both pure moral and social orientations might be found in the same relationships, but as a rule, one orientation predominates" (1975:11). We can release pure more involvement to the orientation predominates in a high power distance society and social involvements to values of the organisation member in a collectivist society.

The level of individualism/collectivism in society will also affect what type of persons will be admitted into positions of special influence in an organisation. A useful distinction in this case is Mertons's "locals" versus "cosmopolitans" (Merton, 1968:447), first published in 1949: the terms originate from a translation of Tonnies' work). The local type is largely preoccupied with problems inside the organisations; this type is likely to become influential in a more collectivist climate. The cosmopolitan type must maintain a minimum set of relations within the organisation; but he or she considers him or herself as integral part of the world outside it. We would rather find cosmopolitans in positions of influence in organisations where a more individualist norm prevails.

The degree of individualism is organisations obviously will depend on many other factors beside a societal norm: We can expect effects of employee educational level and of the organisation's own history and subculture. Also predictable is a relationship with organisation size (Hofstede, G., 1980,p.218).

2.3 Saudi Arabia Organizational Culture

The success of the business systems and the literature related to this identifies there is a need for organisations to continually improve their efficiency and effectiveness,

which can lead to the development and improvement of organisations. The culture of employees is one of the defining factors for organisations as the different factors can influence the uptake of the success of business organisations (Ryan, Chan et al. 1999, Raghuram, London et al. 2001, Crow and Hartman 2002). The cultural setting of Saudis is actually Arab and Muslim. It is widely known that the Saudi setting has a unique culture and heritage, which has been preserved since the inception of the culture (Eid 2011, p.45). Visitors to Saudi, including non-Saudis, are subjected to the same rigorous Islamic law as Saudis. In this regard, different enterprises in Saudi are to a greater extent influenced by the cultural aspects of the Saudi community. When it comes to hiring employees in the enterprises, there will be a clear stipulation that employees, whether of Saudi origin or otherwise, will be governed by similar policies and will follow similar requirements for their enterprises. This is influenced by the religion that is followed in Saudi, which is Islam (Al Mizjali 2001, p.6). The Muslim life thus plays a big role in influencing the business community in Saudi Arabia.

2.4 Success Factors of Knowledge Management Systems

2.4.1 **Knowledge Assets**

According to Green (2004), successful organisational performance measurement is in need of a methodology and system the enables managers to identify knowledge, document knowledge, and value knowledge. Knowledge assets are the major aspects of invention in the 21st century economy, whether their origin is in the services, manufacturing or agricultural sectors. Examples of knowledge assets are: ideas, processes, technologies, intellectual property, skills, competencies, education, customer relationships, professional networks, lessons learned, best practices, methodologies, and techniques (Beames 2003). Tangible assets of labour, physical capital, and raw materials are far less indicative of company's value. In this knowledge era, intangible assets like innovation, relationships, and expertise are far more indicative of a company's value. (Green 2004). The term 'intellectual capital' is analogous for knowledge assets (Castro et al. 2013), Intellectual capital is a two-level concept, such as human capital (knowledge created by and stored in a firm's employees-human resource) and structural capital (the embodiment, empowerment, and supportive infrastructure of human capital) (Castro et al. 2013).

2.4.2 **Knowledge Sharing**

Collaboration both within the organisation and with other organisations is often considered to represent a crucial aspect affecting the overall performance of a company (Boehm 2012). Such as knowledge sharing which remains an essential element in the establishment of knowledge-based working environments within a company. Knowledge sharing within a working environment remains essential as it enables employees to increase their working skills (Bock et al. 2005). Teamwork is also critical to knowledge sharing. The nature of problem solving today is structured in a way where teamwork will enable the organisation to gain the level of support and help as part of the organisational culture; therefore delivering the best possible services (Ke and Wei 2008). Knowledge sharing is further into explicit knowledge sharing and tacit knowledge sharing. According to (Shao et al. 2012), "explicit

knowledge is formal and systematic, and can be achieved through readings of project manuals and team discussions, while tacit knowledge is highly personal, context-specific, subjective, and can be represented in the form of metaphors, drawings, non-verbal communications and practical expertise. It is usually difficult to articulate tacit knowledge through a formal use of language since it is expressed in the form of human actions such as evaluations, attitudes, points of view, commitments and motivation".

2.4.3 **Learning**

In recent years, measurement tools have been validated and used for assessment of organisation-level learning and development (Holten et al., 2000; Kontoghiorghes, 2004; Yang, Watkins, & Marsick, 2004), all of which have direct to indirect connections to learning-related motivation and transfer. To the extent that a major success factor in organisational learning outcomes is employee utilization or transfer of learning to workplace applications, motivation to transfer is a central consideration for human resource development. However, the focus on learning and learning transfer has been either at organisation level or on training-specific transfer. Additionally, specific characteristics or dimensions of organisational culture (Schein, 1992) and subculture (Saffold, 1998) as potential catalyst for supporting employee motivation to transfer have been largely overlooked.

For some time, the strength of organizational culture has been associated with firm performance and success (Barney, 1986a; Shein, 1992). Similarly, learning aspects of organisational culture have been linked with corporate achievement (Cook & Yanow, 1993l Yuki, 2002) and firm financial performance (Ellinger, Yang, & Howton, 2002), (Egan, 2008,p.303-304).

2.4.4 **Leadership**

It has been discussed that quality, culture, productivity and good management are all linked (Shao, Feng et al. 2012). One of the arguments is that high productivity is a result of motivation among employees, which further results in a good climate for work (Stock, McFadden et al. 2007). If the management of an organisation is successful enough to provide the required good climate for the organisation, this will lead to a culture that leads to success (Luis Ballesteros-Rodriguez, De Saa-Perez et al. 2012). A good climate that is the result of good management will result in organisational clarity. It will produce a well-defined structure for decision-making, the integration of different organisational parts, and an amalgamation of different cultures into a unified culture, reflecting the leader's vision. According to Anantatmula (2010), making effective use of knowledge requires intervention of leadership and management because it is associated with incentivizing vision and planned change in direction. The roles of both the leader and the manager are vital at different stages of knowledge management life cycle. Therefore, leadership has a critical role in developing and managing knowledge managment systems.

2.4.5 **Technology**

According to Kemp (2010), the right information technology (IT) systems can be essential enablers of the critical insights necessary to keep enterprise viable and successful. These systems inform and remind decision makers of what the enterprise organisation is, where it is in the world, and how prepared it is to cope with expected and unexpected challenges. Company information systems have become fundamental in enhancing the storage of information regarding employees as well as other aspects of the companies. One of the factors, which need to be taken into account, is that organisational factors must ensure they have the best systems in place (Jun and Kim 2010). The arrival of the Internet and the World Wide Web has made unconstrained sources of knowledge accessible for people. Experts are indicating the rise of the Knowledge Age succeeding the industrial Era. Within organisations, different systems can be used to enable the sharing of knowledge through denoting or acquiring knowledge via knowledge bases, where employees share knowledge electronically and access to shared practices becomes available to other staff members (Khorsheed and Al-Fawzan, 2013).

3 Conceptual Model

Knowledge Management System (KM) is defined as “the process of applying a systematic approach to the capture, structure, management, and dissemination of knowledge throughout an organisation in order to work faster, reuse best practices, and reduce costly rework from project to project”. Knowledge is the foundation of a firm’s competitive advantage, and, ultimately, the primary driver of a firm’s value (Kraaijenbrink, 2010). Organisational culture is considered as a critical factor promoting collaboration, in particular knowledge sharing (Shao et al. 2012). (Škerlavaj, Song et al. 2010) described organisational learning culture is a complex process that refers to the development of new knowledge and has the potential to change individual and organisational behavior. According to (Škerlavaj, Song et al. 2010) Within the competing values framework (CVF) (McDermott & Stock, 1999), organisation learning culture has four different types of cultures: group, developmental, hierarchical, and rational. Based on the related theories and previous studies, a conceptual framework is developed, as outlined in Figure 1.

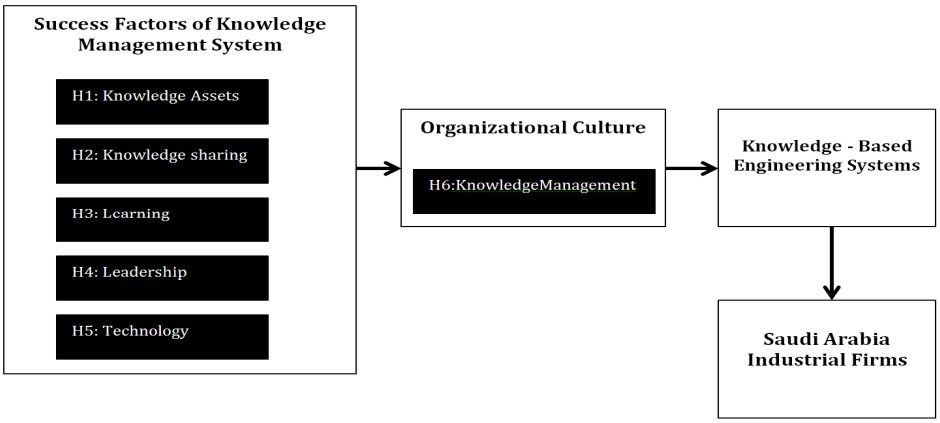

Figure 1: Conceptual model

The theoretical foundations for the research model needs to be evaluated on the basis of the relationship between the variables, which will help in explaining the ways of effective use of knowledge management system. To answer the research question the following hypotheses will be tested.

H1: Organisational culture positively influences the relationship between knowledge assets and knowledge management in a Saudi firm.
H2: Organisational culture positively influences the relationship between knowledge sharing and knowledge management in a Saudi firm.
H3: Organisational culture positively influences the relationship between learning and knowledge management in a Saudi firm.
H4: Organisational culture positively influences the relationship between leadership and knowledge management in a Saudi firm.
H5: Organisational culture positively influences the relationship between the use of technology and knowledge management in a Saudi firm.
H6: Organisational culture positively influences the relationship between knowledge management and knowledge management system use Saudi in a firm.

According to the conceptual model in Figure 1, the main objective of the thesis is to find the relationship between organizational culture and the success factors of knowledge management system such as: (knowledge assets, knowledge sharing, learning, leadership and technology) in Saudi industrial firms.

4 Research Methodology

It has been argued that qualitative research approaches clearly have their strengths in developing grounded theory in regard to the issues under investigation. Such an approach is valuable when looking at for example cultural complexity within an organisation, since little knowledge will exist about issues such as multiple cultural membership, cultural context at the organisational level and the impact on performance (Sackmann, 2001).

This research study intends to apply a mixed method that incorporated both

quantitative and qualitative approaches to validate the research model. Phase one of the research studies will employ a quantitative method, based on the collected data from a questionnaire targeting Saudi Arabian firms from different sectors and industries, a qualitative research method will be then carried out as a second phase of the analysis phase, which will supports the validity of the conceptual model.

4.1 Population and Sample

The population of this study is employees at selected firms in Saudi Arabia. The sample consists of employees who are the users of knowledge management systems.

4.2 Data Analysis Process

Closed-ended questionnaire will be used for survey and open-ended questionnaire will be used for interviews. Before collecting the data, ethics approval will be obtained from ethics committee. The quantitative data will be analyzed using SPSS software and qualitative data collected will be analyzed using Nvivo qualitative analysis tool.

As in any other qualitative study the data collection and analysis occur concurrently. The type of analysis engaged in will depend on the type of case study. Yin (2003) briefly describes five techniques for analysis: pattern matching, linking data to propositions, explanation building, time-series analysis, logic models, and cross-case synthesis. In contrast, Stake describes categorical aggregation and direct interpretation as types of analysis.

5 Conclusion and Significance

Literature search showed that, to date, no research has been conducted on the role of organisational culture on the main pillars of knowledge management towards the effective use of knowledge-based engineering system in the Saudi Arabian firms. Economies are progressively based on knowledge, which is now recognized in Saudi firms, growing into a knowledge-based economy, which delivers a focus on the role of information, technology and learning in economic performance. In order to accomplish it, the organisation and its key advantages ones must identify the main pillars of knowledge management. This research was explicitly looking at Saudi Arabia, a developing country that is embracing a knowledge-based economy.

The input of organisation culture and the knowledge management enablers (such as knowledge asset, knowledge-sharing, learning, leadership and the use of technology) in Saudi Arabia’s enterprise will be of great significance towards the effective use of knowledge management in Saudi context. This research will add a high value to existing knowledge and will be beneficial to firms in Saudi Arabia, who could use the insights analyzed in this study to generate better outcomes.

Food Tourism as an Opportunity of Promoting Local Gastronomy

Roman Švec, Institute of Technology and Business in České Budějovice, Department of Tourism and Marketing, Okružní 517/10, 370 01 České Budějovice, Czech Republic,

Abstract

This paper deals with the topic of Food Tourism and its connection with the local gastronomic products. It compares the demand for the local food in retail stores and in catering establishments: a distinct disproportion between the customers' willingness to find out information about the food origin, while shopping in a store in comparison with buying the food in the catering establishments. The aim of the paper was to identify possible problems in the perception of local food by tourists and to recognize their role when assessing the offer in the catering establishments in the studied area. The conclusion indicates other possibilities for the offer of local food which can be usable for catering establishments. The findings are based on data obtained through questionnaires.

Keywords: Food Tourism, gastronomy, catering establishments, preferences, statement, regional food, local production.

1 Introduction

Catering services are defined by many authors (Beránek, 2004; Long and Chun, 2006), many of them explain the difference between catering service and catering establishments. Catering services are a meaningful business sector across Europe (Horner and Swarbrooke, 2003). The term 'catering service' is defined in the conditions of the Czech Republic in the Act No 258/2000 Coll. (§ 23) as production, preparation or distribution of food in order to serve it mainly in the hospitality trade, in the cases of serving refreshments and serving meals as a part of both accommodation and tourism services. From the marketing point of view, Middleton (2009) defines catering services as a combination of a product (food or drink) and a service (the culture of dining, atmosphere, overall impression). Quality of catering services is an important factor of the perception of quality of accommodation (Švec et al., 2012).

Catering services fulfil several functions. According to Indrová (2004), catering fulfils three functions (basic function = ensuring nourishment during the day; complementary function = snacks between meals; social-entertainment function = creating conditions to meet the needs of social communication, meetings, entertainment, distraction). On the contrary, Smetana and Krátká (2009) recognize only two functions – basic and supplementary; they do not mention the social-entertainment function. However, many other authors mention the social aspect of catering services (Beránek 2007; Poláček and Němčanský, 2011). The above mentioned businesses form a part of the so called hospitality industry, which is a notion mainly used in the out of European countries and overseas literature (e.g. Saleh, 1991; Collin, 1994; Parks & Haemoon (1997); Bolela, 2000; Erdly & Townes, 2010).

It is necessary to distinguish between the terms 'catering services' and 'gastronomy'. Kinton and Cesarini (1984) describe gastronomy as a discipline about gourmandise and culinary art. Patúš, Gúčik and Marušková (2011) agree with this statement. Another definition considers gastronomy as a structure of relationships between food and drink which contains the 'art of table' – this 'art of table'

is understood as the art of creating something (Holub, 2004). Gastronomy has undergone through the historical development, as well as using special terms. The terms 'gastronome', 'gourmand' (= gourmet), 'culina' (= cuisine), 'culinary' (= cookery) spread in Europe, especially in the 18th century when French gastronomy became a phenomenon thanks to the boom of France as the Europe's economic and political power.

Currently, many world gastronomies notice the trend, laying in clarifying national or regional dishes to the participants of tourism. Besides this, it is shown to the local inhabitants what is in fact their national gastronomy. Thanks to this trend, Culinary tourism has been developed (Smith, 2008), sometimes it is called Gastronomy tourism (Hjalager, Richards, 2003), or Gastronomic tourism (Jalis, Zahari, Zulkifly, Othman, 2009). The authors use different terms, but their understanding pervades mutually. This is one of the newest trends in tourism; some sources consider the year 2001 as the year of its birth (Karásková, 2013).

In the Czech terminology, e.g. Kotíková (2013) deals with this topic and speaks about gastronomy tourism. Orsáková and Obůrková (2004) define it as travel for unique and remarkable culinary experiences. Typical activities are visits of special restaurants, fishing boat tours, beer festivals, visits of food factories etc. (Orieška, 2010). In the year 2012, World Food Travel Association recommended to use the term 'Food travel' which is mentioned e.g. by Williams, Williams, Maktoba (2014) and Banerjee (2015). However, this term was used by some authors earlier (e.g. Hall, Sharples, Mitchell, Macionis and Cambourne (2004). Food travelling is explained as travelling focused on learning about gastronomy and tasting national and other culinary specialities. It can be also a visit of gastronomic events, companies or cooking classes organized by well-known experts and famous restaurants. This concept is summarized e.g. by Long and Chun, 2006) who states this kind of tourism is about food as a subject, means, objective and a tool of tourism. Food Tourism consists of many parts such as beer tourism, tourism for wine, chocolate etc. (WFTA, 2012). Mitchell and Hall (2003) present the participants' typology of this kind of tourism – these authors consider the participants' motivation as a factor for the division. Food Tourism has become also a part of the travel agencies' offerings. Hiking or biking in wine regions, visits of the European Christmas markets etc. have become a classic offer (Yeoman, 2008). Authors who focus on Food Tourism in the Czech Republic (e.g. Palatková, 2006) state the Czech product should be based on the following elements: brewing, folkloric celebrations related to the gastronomy, wine tradition and production of the traditional alcoholic drinks (Carlsbad Becher liqueur, slivoviz = plum brandy).

Fresh, local, organic, sustainable and seasonal products and preserving local culinary traditions are crucial for the Food Tourism concept (Ryšavý, 2010). Regional dishes and regional ingredients have been the most characteristic trends in the today's gastronomy for several years (Štensová, 2013) and restaurants offering this type of food have promoted themselves also in the Czech Republic. The growing interest of consumers as well as of producers and marketers in regional food not only in catering, but also in purchasing food is confirmed for instance by Chalupová, Prokop and Rojík (2012) and Ritz et al. (2011). Mcentee (2010) states, customers seeking for this type of food are trying to find an alternative to unified global brands. Producers could intend to use the concept of local food to sell their production for better price compared to ordinary national or even supranational selling channels (Doležalová et al., 2014). There are lots of definitions of a regional product in the literature. However, there is no consensus in their use. For instance, Ittersum, Candel and Meulenberg (2003) define the regional product as a product that is connected with the region where is considered as a traditional and it is made from local ingredients. Traditional procedures, handmade production and environmental friendliness are frequent requirements to the regional products (Thilmany, Bond and Bond, 2008). Some authors (e.g. Pícha, Skořepa and Navrátil, 2013) distinguish the concept of a local product which is associated with local production or directly with production from the particular catering establishment. Regional brand is often connected with the quality of products – this has been proved in the research by Lobb, Arnoult, Chambers and Tiffin (2006).

The quality in gastronomy is the ability of a product or a service to meet the needs, requirements and expectations of customers (Zimáková, 2010). Authors from the Management Consulting Group (2008) agree with this point of view which means that the quality of a service is the ability to meet

customer's expressed, tacit and unconscious requirements. Other authors state that a quality service does not only meet the expectations, but exceeds them (Indrová, Houška, Petrů, 2011). The quality in gastronomy is the satisfaction within the accepted price and customer's expectations which include basic qualitative factors such as safety, hygiene, availability of accommodation and catering services and harmony with human and natural wealth (Anholt, 2009) and also with staff (Jacob, Guéguen, Boulbry, 2014). Based on many findings, quality management seems to be the most important protective factor against losses of guests (Chen and Tsai, 2007) and the perception of quality is the basic predictor of satisfaction not only with a particular business organisation, but with the whole stay (e.g. Bigné et al., 2001; Jin, He and Song, 2012; Petrick 2004; Yuan and Jang, 2008).

Studied area

The studied area České Budějovice is the capital of the region, as well as the center of the South Bohemia tourist region (Cetkovský et al., 2007; Navrátil, Pícha and Martinát, 2012; Navrátil, Pícha and Navrátilová, 2012) and with approx. 94,000 inhabitants, it is ranked at the ninth place in the Czech Republic. The dimension of its cadastral area is approx. 5,560 ha, where the built-up area represents 601 ha. The lowest altitude is 379 m.a.s.l. and the highest altitude is 528 m.a.s.l. (ČSÚ, 2013). České Budějovice was founded in 1265 and became a commercial and handcra center of the entire region (c-budejovice.cz, 2014). The historical center of the town was declared a monument reservation in 1980 and includes nowadays approx. 250 cultural monuments. The contiguous zone of protection comprises more recent suburbs with an additional more 50 monuments. The existing building monuments cover all style periods (i-cestování.cz, 2012). The current offer of tourism in town could be based on five main pillars: historical monuments, culture, gastronomic tourism, exhibitions and interesting sites in the surrounding area (In Puncto, 2008). As for the tourism supply, the studied area disposed with the important historical objects, but in comparison with the monuments in proximity of the town, those in the town are not as well known. According to the statements of experts, the town has a lack of significant attractions that are important for tourism. On the contrary, there is a good structure of accommodation capacities. Thanks to the rich offer of cultural programs, the studied area has become a base for visitors' travel destinations not only in the area of České Budějovice, but also within the entire South Bohemian Region. Another important role is also played in České Budějovice in gastrotourism, particularly related to the Budvar Brewery, as well as the tradition of exhibitions (shortened according to In Puncto, 2008). The accommodation sector and the catering industry employs 2,424 people in the area (ČSÚ, 2013), which is cca 5.1 % of the total economically active population (47,185) in this area (ČSÚ, 2014).

2 Aim, research material and used methods

The aim of the research was to determine the preferences of tourists within the offers of regional foods in catering establishments, as one of the possible elements for their further development. The research was conducted through questionnaires, placed at the reception desks of the accommodation facilities in the studied area from November 2015 to January 2016 (in this way, it was guaranteed completion of questionnaires by tourists rather than residents). Questionnaire's availability at the reception desks implicated a random sampling of respondents.

In the questionnaire, there were 14 questions (from them there are 3 segmentation questions and the rest of questions focused on the evaluation of partial aspects that may influence the offer of local foods and dishes in the visited catering establishments). In total, 620 respondents were questioned in catering establishments (especially in hotels). 65 % of respondents were women and 35 % men. The questionnaire was completed by 15.8 % of respondents aged 18-26 years, 26.1 % of respondents aged 27-35 years, 34.8 % of respondents aged 36-45 years, 11.2 % of respondents aged 46-65 years 11.9 % of respondents aged 65 and more. Answers to questions were designed as a scale from 1 to 5 (1 = definitely agree, 2 = rather agree, 3 = I can't decide, 4 = rather disagree, = 5 definitely disagree).

Respondents' answers were processed and expressed in absolute and relative frequencies in the summary table. Answers were subsequently analysed and presented through graphs. Finally, the

synthesis of the obtained data was carried out and several opportunities for further development in the studied area were identified.

3 Results

The first statement in the questionnaire was 'I notice on the menu whether the dish is prepared from ingredients from local producers or growers' (see Fig. 1). Respondents disagreed with this statement (54 %); they do not search this information (independently on their age and gender). The answers can be influenced by the fact that Czech catering establishments are not accustomed to displaying this kind of information and customers do not seek for it.

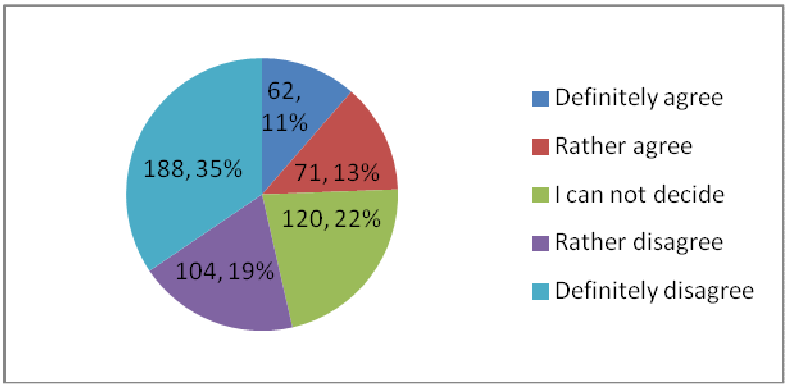

Fig. 1: Statement 'I notice on the menu whether the dish is prepared from ingredients from local producers or growers'
Source: Own processing.

The second statement was 'if I find on the menu that the dish is made from ingredients from local producers, I consider ordering it more than ordering other dishes' (see Fig. 2). Similar to the first statement, a large number of negative answers were identified. However, their sum of relative frequencies is lower (44 %) than in the first statement. The number of respondents who are not able to decide is roughly the same as in the first statement.

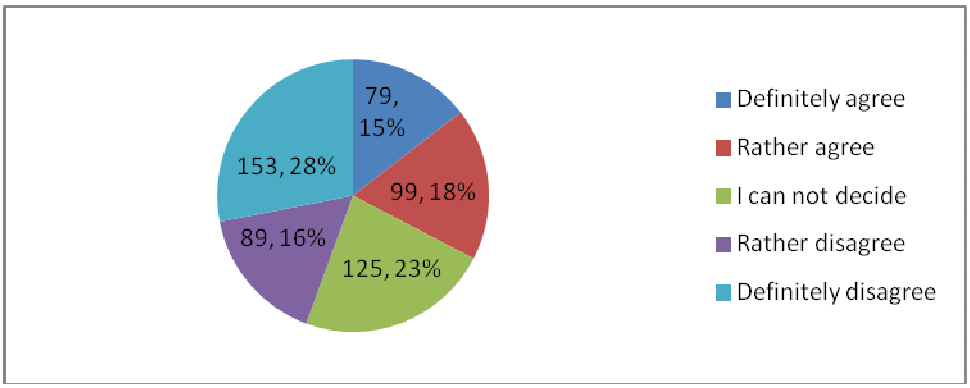

Fig. 2: Statement 'If I find on the menu that the dish is made from ingredients from local producers, I consider ordering it more than ordering other dishes'
Source: Own processing.

The third statement was if it is not stated on the menu, I ask proactively whether the dish is prepared from local ingredients' (see Fig. 3). This statement was the most rejected by respondents from the whole questionnaire. 80 % of respondents do not ask proactively and only 4 % of respondents do it proactively.

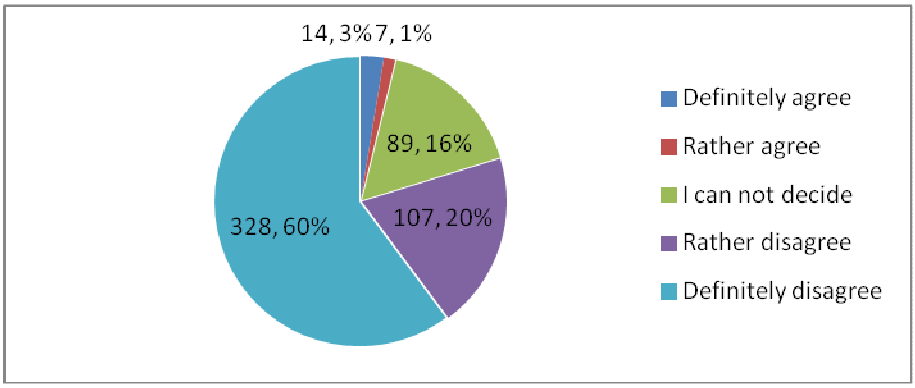

Fig. 3: Statement 'If it is not stated on the menu, I ask proactively whether the dish is prepared from local ingredients'
Source: Own processing.

The fourth statement was 'I look for such catering establishments which declare they prepare dishes from ingredients by local producers' (see Fig. 4). The purpose of this statement was to find out how much the catering establishments what declare preparation of dishes from ingredients from local producers are preferred. It is obvious the majority of negative answers (like in the previous statement dealing with the proactive approach to asking about the origin of ingredients). However, significant differences between the generations were revealed. In the age category 46-65 years, the total sum of answers 'definitely agree' and 'rather agree' was 75 %, which is considerably more than in the case of younger respondents where this sum was only 18 %.

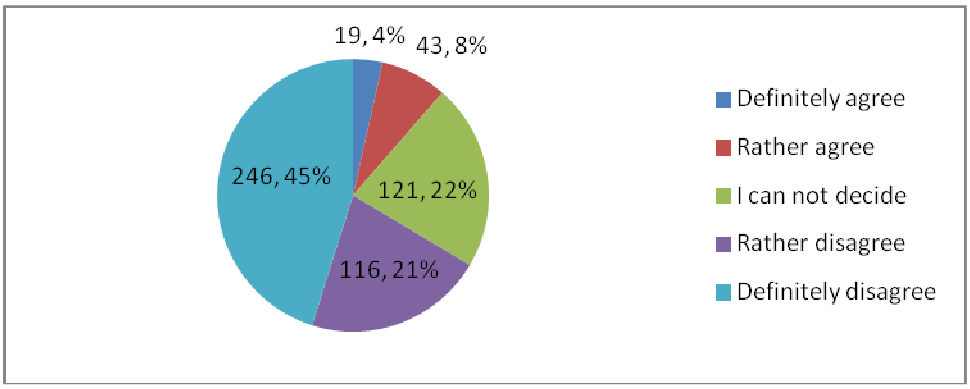

Fig. 4: Statement 'I look for such catering establishments which declare they prepare dishes from ingredients by local producers'
Source: Own processing.

The following statements focused on the fact whether the information about local suppliers and used ingredients from which the dishes are prepared appears to be attractive information for guests in catering establishments. The first statement was 'I would like to see a brief presentation of local suppliers on the menu' (see Fig. 5). Answers to these statements were more negative (51 %) – it was

similar to the previous statements. The presentation of local suppliers is not required by respondents regardless of their age or gender.

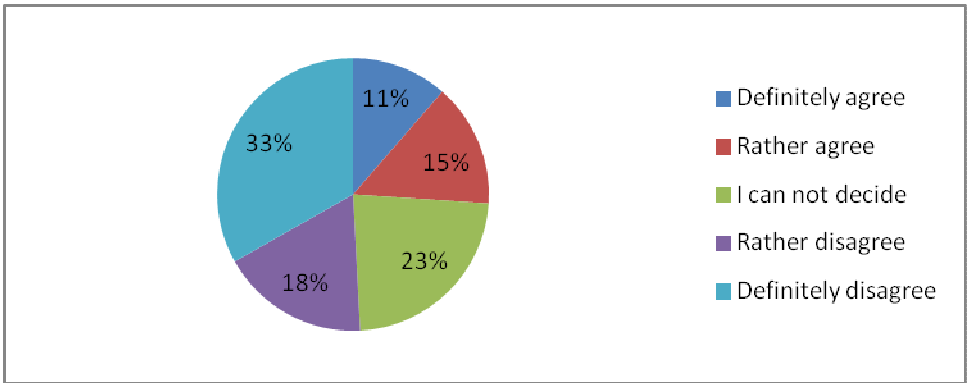

Fig. 5: Statement 'I would like to see a brief presentation of local suppliers on the menu'
Source: Own processing.

The next statement was 'I would like to see on the menu information on the origin of ingredients from which the dish is prepared' (see Fig. 6).

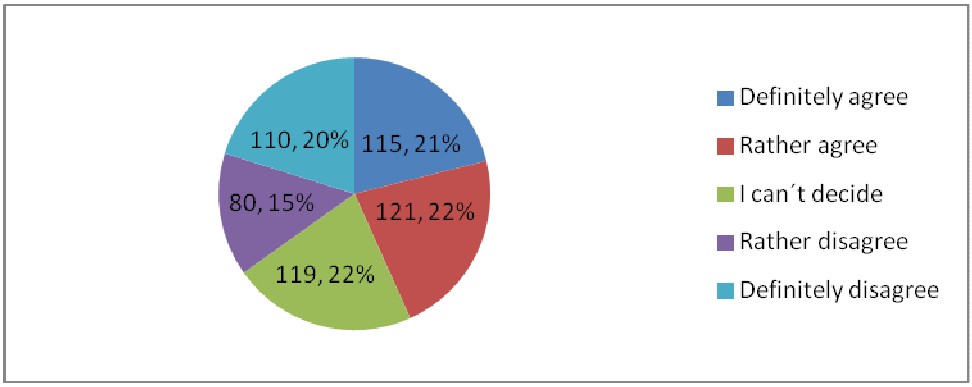

Fig. 6: Statement 'I would like to see on the menu information on the origin of ingredients from which the dish is prepared'
Source: Own processing.

It is obvious, 43 % respondents definitely agree or rather agree with it (see Fig. 6). Currently, there is a duty in the Czech Republic which is to put a list of allergens in food in an accessible place for customers. While producers or traders have to state the origin of food, in the catering establishments this is not common. A significant statistical difference was identified - there is a certain dependence on the respondents' gender. This difference is shown in Tab. 1.

Tab. 1: Absolute and relative frequencies related to the statement 'I would like to see on the menu information on the origin of ingredients from which the dish is prepared

Respondents	Definitely agree		Rather agree	
	absolute frequency	relative frequency	absolute frequency	relative frequency
Female	87	76 %	88	73 %
Male	28	24 %	33	27 %

Source: Own processing.

The two following statements explain respondents' preferences in relation to the Czech cuisine and local cuisine. The first of these statements was 'I prefer catering establishments offering Czech cuisine' (see Fig. 7). There were two approximately equally large groups that agree and disagree with this statement. In the group with answers 'definitely agree' and 'rather agree', there were identified different preferences with regard to the age categories of respondents – it is shown in Tab. 2 (in this case, respondents' gender does not cause differences in preferences). The positive reaction was proved in the age category 46-65 years what is similarly numerous as the age category 27-35 years, however, the number of positive answers was significantly lower in the last mentioned age category.

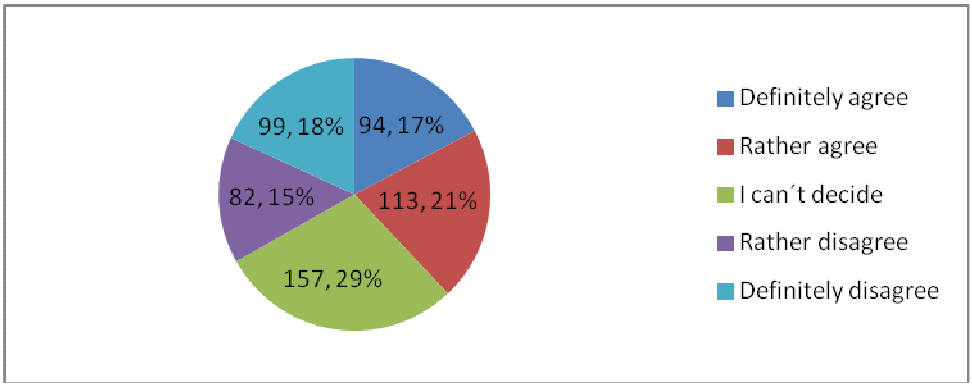

Fig. 7: Statement 'I prefer catering establishments offering Czech cuisine'
Source: Own processing.

Tab. 2: Absolute and relative frequencies related to the statement

Age category	Absolute frequency	Relative frequency
18 - 26	15	7,20 %
27 - 35	32	15,50 %
36 - 45	18	8,70 %
46 - 65	116	56 %
65 and more	26	12,60 %
Total	207	100 %

Source: Own processing.

The second of the statements dealing with the respondents' preferences in relation to the Czech cuisine and local cuisine asked whether respondents prefer catering establishments which offer local cuisine (see Fig. 8). The amount of both positive and negative answers was approximately equal; it is

worth noting that there was a significant group of respondents who answered 'I can not decide' (34 %). It means they were not able to express their preferences.

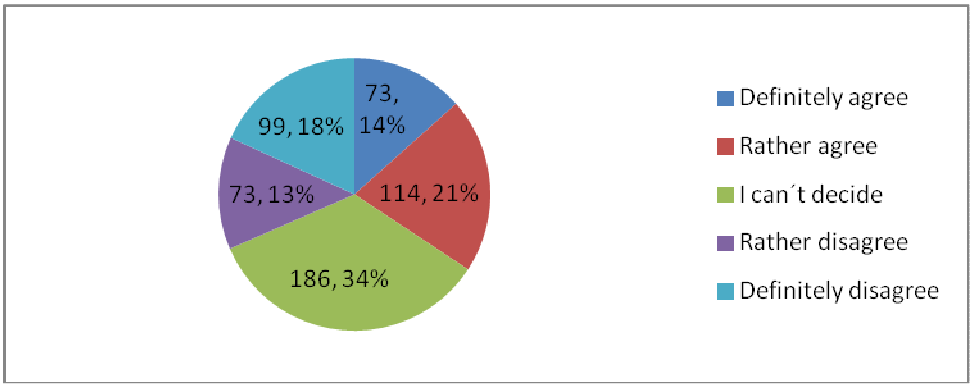

Fig. 8: Statement 'I prefer catering establishments which offer local cuisine'
Source: Own processing.

With the next statement 'I am interested in the origin of the ingredients in restaurants', 15 % of respondents agree and 23 % of respondents are unable to decide (see Fig. 9). This statement was similar to the above introduced statement 'I look for such catering establishments which declare they prepare dishes from ingredients from local producers' – the purpose of this similar statement was to determine the truthfulness of the respondents' answers because fundamental differences of answers to these statements would be problematic when accessing the credibility of the obtained data. Fortunately, the detailed analysis does not show any large discrepancies in respondents' answers.

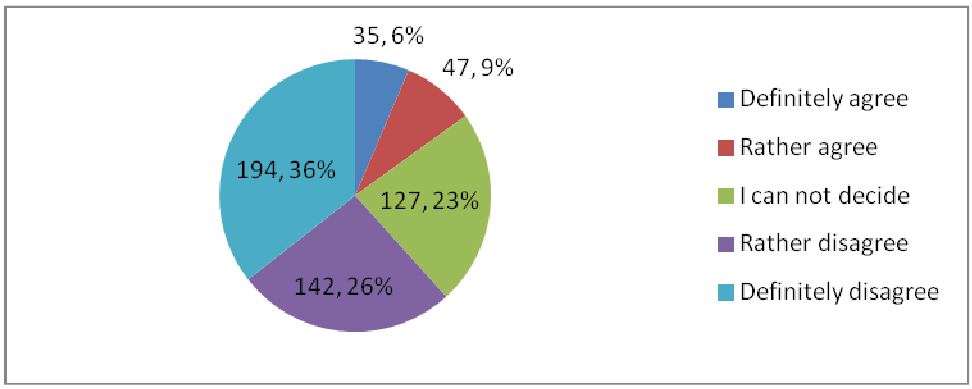

Fig. 9: Statement 'I look for such catering establishments which declare they prepare dishes from ingredients from local producers'
Source: Own processing.

The next statement in the questionnaire was 'I am willing to pay more for fresh dish prepared from ingredients from local producers' (see Fig. 10). Again, this statement divided the respondents into two equally large groups. The authors' expectation that respondents' answers will be influenced by their income, was not confirmed. On the other hand, there was found out a connection between the answers 'definitely agree' and 'definitely disagree'. Respondents belonging to the age category 46-65 years, expressed their agreement. The age category 18-26 years disagrees with this statement – this category was smaller but the response rate 'definitely disagree' was nearly 90 %.

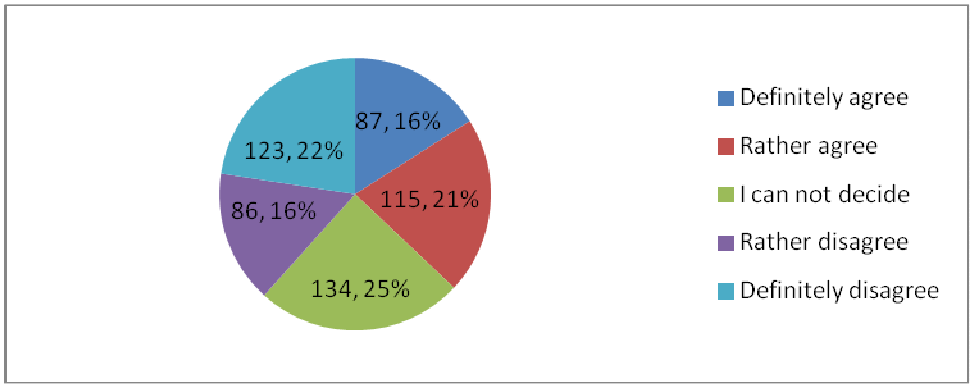

Fig. 10: Statement 'I am willing to pay more for fresh dish prepared from ingredients from local producers'
Source: Own processing.

The last statement was 'when I travel, I like learning local products and local gastronomy' (see Fig. 11). It means, this statement tried to find out the willingness to devote the time on holiday to the Food Tourism. When evaluating the obtained answers, there was the highest number of positive responses (67 %) from the entire questionnaire. Positive answers predominated in all age categories and across respondent's gender. No significant differences in answers were identified (in the context of segmentation criteria).

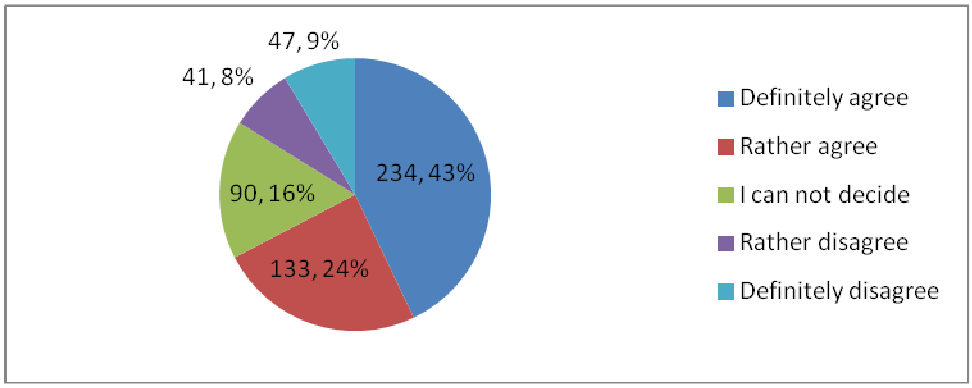

Fig. 11: Statement 'When I travel, I like learning local products and local gastronomy'
Source: Own processing.

4 Conclusion

There has been found out the interest in the studied type of tourism – many authors, e.g. Hjalager and Richards (2003), Willams, Williams and Maktoba (2014) consider it perspective. This type of tourism is based on the cultural traditions of a particular nation and just traditions are nowadays one of the main motives for travelling (Goeldner and Ritchie, 2009). The European literature considers the catering services as the basic services of tourism (Gúčik, 2010) - this fact had probably an impact on the respondents' willingness to complete the questionnaires. Regional or local food is a very often researched topic, primarily as for the preferences in retail. In the Czech Republic, there is the popularity of the farmers' markets and small shops which offer local products. The offer of the local products is also visible in the retail chains. Food Tourism is based on the offering local cuisine to participants of tourism.

However, the lack of the interest in the information about the food origin was found out in catering establishments in the studied area. Although some research studies, conducted in retail units, show clearly that some groups of customers focus on local production in the field of gastronomy, it was not confirmed in this research (see answers to the first statements in the questionnaire). The statement no. 4 showed clearly the disinterest of respondents in the offer of such catering establishments what declare the origin of the food. The age category between 46-65 years, irrespective of their gender, prefers Czech gastronomy. It implicates the main effort to promote the offer of local products should be focused on this segment.

The effort to get answers from tourists what they consider to be the typical gastronomic products or typical food has been successful according to the age of respondents. Older respondents answered more fully than respondents of the younger generation. This may relate to the fact that preparing dishes from regional ingredients is promoted in many popular TV cooking shows, which were often mentioned by respondents in the questionnaires. The overall willingness to explore gastronomy and local products while travelling was proved due to the final argument of the questionnaire, but the results contrast sharply with statements that examine the interest in information regarding the local food producers and their markings on the menu.

Based on the results, we can say that the topic of the regional foods is known mainly due to food buying. It is also demonstrated by the results of our conducted researches what have not been published yet. Despite the willingness to explore regional products and regional cuisine when travelling, respondents stated they are not willing to seek for such catering establishments that offer local products and they are not even interested in this kind of information on menus. These results give the evidence there is an insufficient promotion of the local gastronomy and its benefits.

Further research should be focused on the identification of such tourists' segments which are searching for these products and on mapping of the regional offer in the catering establishments, including subsequent recommendations for expanding the awareness of regional products in catering establishments.

Innovation Potential Measured By the Hard and Soft Data

Hana Scholleova, Czech Technical University in Prague, The Masaryk Institute of Advanced Studies, Department of Economic Studies, Kolejní 2a, Prague 6, 160 00, Czech Republic, hana.scholleova@cvut.cz

Abstract

Innovation is important, both from a macroeconomic and microeconomic perspective. Anything that is important should have its goal and therefore all activities of the subject should follow a direction to achieve such goals. Managed can be only those things that can be measured. That implies the desire to measure innovation. For this purpose, various scales are being created. We are always choosing between two options of these scales - tough standards are objective, clearly quantifiable, but can measure only the past. Whereas companies need to manage the future, these measures are only partially applicable. Therefore scales which focus more on the company's potential and how to valorize it are being created. It is a measure based on a survey of managerial infrastructure for the management of the company, layout resources and their valorization. Subsequently with the use of converters (scaling), findings are converted into hard data. The aim of this article is to assess the relationship between the hard and soft data in a case study based on the evaluation of companies using soft data and linking them with hard data to evaluate the potential of the company.

Keywords: enterprises innovation, SAII, Czech Republic

Introduction

Hard scales are used at the macro level for comparing countries. Known indices (Innovation Union Scoreboard, 2015) use only hard data, collected several years ago. These measurements cannot be used by companies – they are intended for use by political and economic representatives of states which have the authority to use political tools to influence development in their countries – such as tax benefits for certain types of business, reducing bureaucracy of certain processes, etc. The support of countries in this matter can be both direct and indirect, as well as financial (subsidy) or nonfinancial (removal of administrative barriers). Various scales, regularly evaluated at a national level, which are drafted on a combination of hard and soft data are being used to identify any barriers. Eurostat coordinates the issues, data collection and their processing method, therefore it is possible to perform international comparison. Once in every two years the Czech Statistical Organization (Czech Statistical Organization, 2016) evaluates the position of Czech companies in the field of innovation.

In 2016 a recent survey with data collected within 2010 – 2012 has been released, survey results with data collected within 2012 – 2014 has not yet been issued. It is obvious that the data are an interesting impulse for monitoring the time series, but from the perspective of development and speed are very outdated. The benefit of this kind of data investigation for companies is the possibility of comparison with an average company of a similar focus. It is possible to define the amount of revenue acquired by other firms on innovative products, how much they donate to science and research, how they operate with subsidies and the way the spread cost of individual items of innovation activities, etc. Based on soft data, it is very interesting to observe the innovation barriers and the importance of entities' cooperation in innovation which is evaluated in calculations of IHIS CR. The aforementioned measures, however, do not address the required future direction of the companies. Companies are still searching the best unit to measure the potential for innovation in the future. In the years 2015 - 2016 the SAII index was developed in the Czech Republic within the project "Measuring evaluations", which was based on soft data. (Špaček, 2015)

Research methods

The starting point were already existing metrics (The Global Innovation Index, 2014; Innovation Union Scoreboard, 2015; Vacek, 2010).

The SAII index is designed to meet these requirements:

- focus on future
- constant assumptions on company's innovation behavior (both sources and long-term conceptual work with them)
- goal is not the rating, but the long-term motivation for improvement

The solution was a set of questions on soft characteristics of the company, the first stage was verified on a small sample of firms but showed a large amount of indicative questions (Jiřinová, 2015).

In the second stage, the questionnaire was modified as follows:

- exclusion of questions where the subjects respond the same way
- insertion of comparable metrics (ratio x absolute indicators)
- inserting questions on infrastructure and internal management and pro-innovation culture

Verification was conducted on 40 subjects and showed that there is still a large amount of questions with a low degree of dispersion and due to misunderstanding of the question, respondents are hesitant to provide accurate answers. To increase the clarity, the questionnaire was adapted to be more detailed in terms of scaling each question (range 0-2-3-5instead of yes-no answers) and the answers are more verbally described. The single number success evaluation (innovation potential in [%] of the maximum possible value), has been replaced by a success evaluation in five areas, namely:

- Conceptual activities
- Resources
- Management infrastructure
- Operational management of the innovation process
- Financial/Non-financial indicators

Despite the problems with hard scales, it was decided to include financial issues – which are in line with the terms of what innovative financing tends to monitor, as well as what is pursued by the transnational investigation.

Selected characteristics of the soft type and percentage of applications in companies on fig. 1.
The second phase of the questionnaire was verified on 40 subjects.
Set of surveyed companies ranged mainly in manufacturing industry, with a certain level of innovation activity. Data were obtained by direct addressing, on the basis of previous contact of actions relating to long-term efforts to improve innovative activity.

Furthermore, soft data should be compared with hard data, especially with the financial prerequisites for innovation.

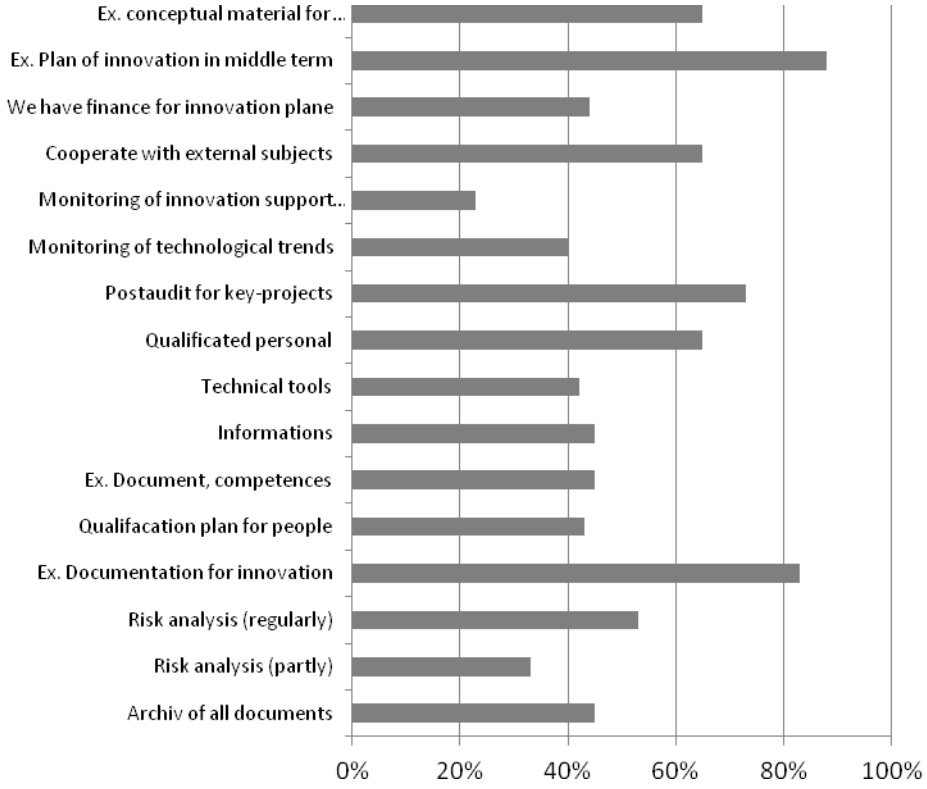

Fig 1. Evaluation presumptions of innovation - soft data, Source: own

Given that innovation is an essential prerequisite for competitiveness, it is appropriate that the scope of innovation potential partially overlaps with competitiveness precautions. For this purpose we use the research (Scholleová, Čámská, 2015), marking the indicators which are significant for identifying the innovative potential - in advance. It does not only take into account the indicators that evaluate the actual financial performance of the company, but indicators that may cause future positive development of the company.

Such indicators are displayed in table 1.

Table 1: Indicators of significant potential for innovation for the company, Source: Čámská and Scholleová (2015)

No	Of short	Explanation	Ideal value
1	OE/OR	Share of operating expenses on operating revenues	minimum
2	I(VA)	Annual growth of value added	maximum
3	I(S)	Annual growth of operating revenues	maximum
4	I(TA)	Annual growth of total assets	maximum
5	I(PE)	Annual growth of personal expenses	maximum

For evaluation it was necessary to work with the hard data of the participating companies. Although companies in the Czech Republic have a disclosure obligation to the accounts given by law, it turned out that it does not comply with 9 companies. 12 of the remaining 31 companies were impossible to analyze because of the incompleteness of the necessary data or incomparability of the data (change in length of the fiscal year, the transformation of society, etc.).

Structure of the resulting firms analyzed in table 2, where in the first column contains the estimated number of all firms in the country in groups of small sized (total assets 0-10 000 EUR), medium sized

(total assets 10 001 EUR - EUR 50 000) and large sized (total assets are more than EUR 50 000) business.

The second column is therefore the share structure of all companies (RF) in the Czech Republic.

Since we have worked with innovating firms, the structure had to be adjusted to take % of data from innovative companies provided in calculations by Czech Statistical Organization (Czech Statistical Organization, 2016) relating to individual groups (RI), which are shown in the next column.

Share of innovative enterprises in the total of each type (RIC) is then calculated based on a formula bellow

$$RIC = RF \cdot RI \quad (1)$$

The data in this column are then converted into a theoretical structure of firms in the country (TRIC) base on a formula bellow

$$TRIC = RIC / \Sigma RIC \quad (2)$$

We can compare the companies according to the computed theoretical structures included in our evaluation, the structure is in the last column of table 2. We can see that it is not a representative data sample, especially due to the greater amount of large firms.

Table 2: Structure of data sample - comparison with theoretical structure, Source: own processing by (Czech Statistical Organization, 2016)

company	Companies in Czech Republic	RF	RI	RIC	**TRIC**	**Research data set**
Small	16 941	76%	38%	29%	**66%**	**58%**
Medium	4 171	19%	58%	11%	**25%**	**16%**
Large	1 141	5%	79%	4%	**9%**	**26%**

Furthermore, our investigation will be viewed as a pilot survey and individual case studies.
Results of soft evaluation are expressed in [%] of points of the possible points obtained of a positive response:

$$SAII = G / P \quad (3)$$

where
G - number of points received,
P - the number of points that could be obtained

In figure 2, you can see the distribution of success of all businesses in the soft scales.
Monitored companies are colored dark.
We can see that companies have available hard data spread across a range of value index SAll.

In selected companies we evaluated the degree of dependence between hard data and innovative potential of the overall index SAll. Correlation coefficient was used for evaluation.

In table 3, we can observe the correlation coefficients, which measure the relationship between hard data and SAll. Stronger degree of correlation is between revenue growth and value added growth. SAll has a weak to moderate correlation with hard data. To continue to work with the assumption of certain independence, we have excluded it from the assessment of hard data I (TA).

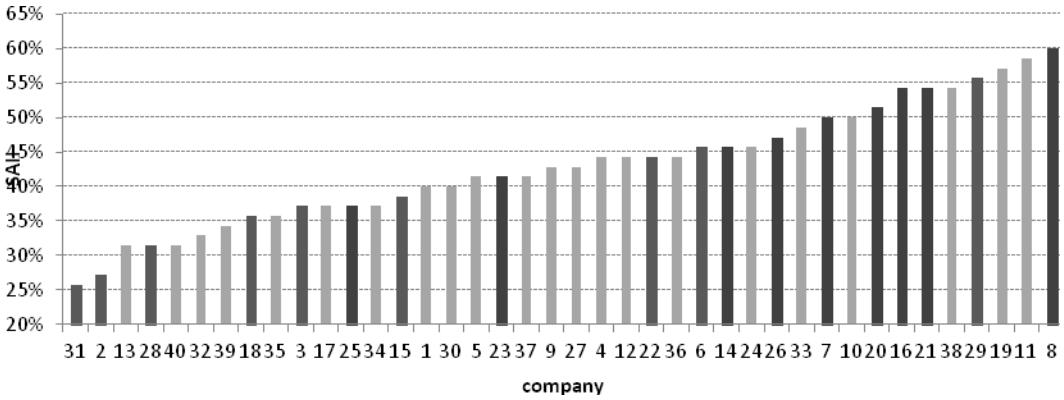

Fig 2. The SAll in a pilot survey for selected transparent companies, Source: own

Table 3: Correlation coefficients, Source: own

	OE/OR	I(VA)	I(S)	I(TA)	I(PE)	SAII
OE/OR	1,00	-0,24	-0,23	0,24	-0,05	0,12
I(VA)	-0,24	1,00	0,90	-0,53	0,04	0,01
I(S)	-0,23	0,90	1,00	-0,42	-0,02	-0,08
I(TA)	0,24	-0,53	-0,42	1,00	0,55	0,63
I(PE)	-0,05	0,04	-0,02	0,55	1,00	0,50
SAII pilot	0,12	0,01	-0,08	0,63	0,50	1,00

Therefore, only indicators OE/ OR, I(VA), I(S) and I(PE) will be used for further work with the evaluation of the financial potential. In order to compare the effectiveness of hard and soft measures, a summary indicator HARD will be calculated from these values.
The problem in input is that one of the indicators is desirable to minimize (OE/OR), while maximization is desired in another one.

For the conversion of the value of each indicator, an ideal value is calculated, and all sub inputs are converted into percentage of the ideal value. HARD endpoint is then the average of the values of input parameters.

Calculation for all respondents is in the table 4.

Indicated in table 4 is the comparison with the value SAll and completed indicators for current business success ROA, which is calculated as EBIT/total assets.

Table 4: Calculation and comparison indicators HARD, SAII and ROA, Source: own processing

	Value of				% of ideal value				HARD	SAII	ROA
company	OE/OR	I(VA)	I(S)	I(PE)	OE/OR	I(VA)	I(S)	I(PE)			
1	0,10	0,77	0,81	0,7	76%	19%	42%	47%	45%	40%	3%
2	0,97	2,17	1,95	1,5	8%	53%	100%	93%	54%	27%	3%
3	0,90	0,95	1,00	1,0	9%	23%	51%	64%	28%	37%	8%
6	0,86	1,11	1,07	1,0	9%	27%	55%	64%	30%	46%	3%
7	0,18	1,12	1,00	1,0	43%	27%	51%	64%	41%	50%	-1%
8	0,77	1,13	1,09	1,0	10%	28%	56%	67%	31%	60%	16%
14	0,08	4,07	1,27	1,1	100%	100%	65%	67%	88%	46%	10%

15	0,93	0,67	0,73	0,6	8%	16%	38%	40%	21%	39%	3%
16	0,72	1,13	1,17	1,0	11%	28%	60%	63%	33%	54%	31%
18	0,31	1,41	1,19	1,0	26%	35%	61%	66%	40%	36%	7%
20	0,37	1,19	1,15	1,0	21%	29%	59%	67%	36%	51%	7%
21	0,74	1,02	1,05	1,1	11%	25%	54%	71%	30%	54%	7%
22	0,87	1,43	1,24	1,3	9%	35%	64%	81%	36%	44%	15%
23	0,83	0,98	0,93	1,2	10%	24%	48%	74%	27%	41%	52%
25	0,10	3,15	1,41	0,9	77%	78%	72%	55%	76%	37%	9%
26	1,00	0,71	1,13	0,9	8%	18%	58%	57%	28%	47%	2%
28	0,38	2,31	1,85	1,6	21%	57%	95%	100%	58%	31%	9%
29	0,96	1,05	1,32	1,1	8%	26%	68%	70%	34%	56%	4%
31	0,99	0,98	0,96	1,0	8%	24%	49%	66%	27%	26%	14%
The best	0,08	4,07	1,95	1,6							

When comparing the observed effect on economic performance benchmarks monitored using ROA (see Fig. 3) we can see that the influence of the hard characteristics of innovation on the actual performance of the company is highly debatable. Companies that have high index HARD, but poor performance in soft scales, are achieving less than ROA firms that focus on the management of soft features, although they have lower HARD assumptions.

The best-performing companies are those, which use both hard scales, focusing on financial assumptions and soft scales, focused on design, strategy and management of infrastructure to control.

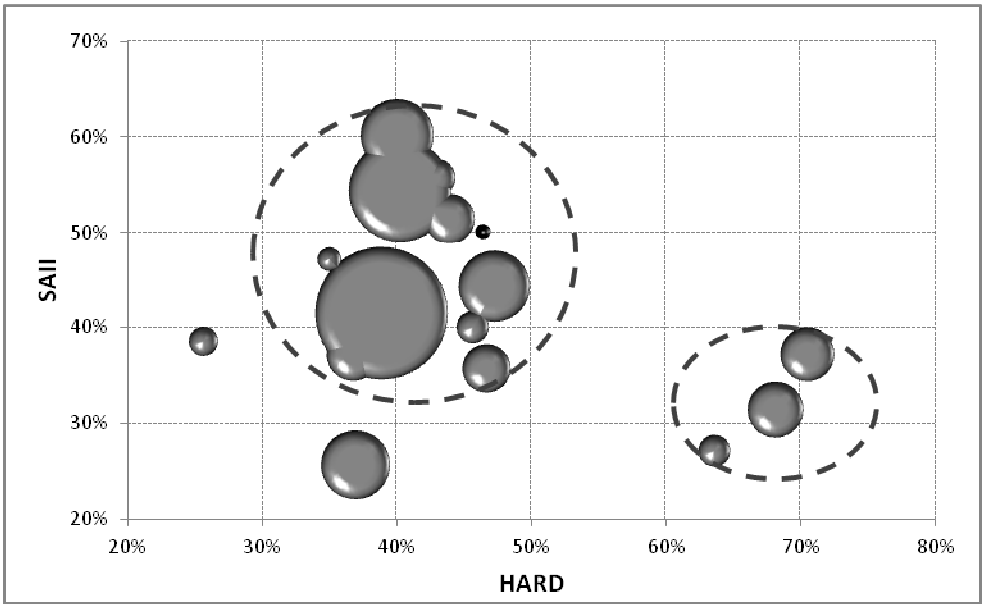

Fig 3. Relationship between power (ROA), and the preconditions for innovation companies, Source: own processing

Conclusion

Innovation is an important prerequisite for the permanent survival of any company. Countries and businesses, who attempt to measure their innovation capability, use scales that are often based on past results, or its presumptions without assessing the possibility of their fulfilment. Assumptions are financial, non-financial, well measurable or estimable only. It turns out that soft scales are often much more important for the future development of the company. The article also compares the

results of a group of companies, which has been evaluated using both hard and soft scales and compared with consequent financial results. It turns out that the best results are achieved by companies that have good (or average) results both in financial assumptions of innovation potential and in assumptions hardly quantifiable (conceptual activities, strategy, management infrastructure, operational management).
